good plan; also, to remember that 10 per cent. profit on material and labor represents on a job of from $200 to $1,000 simply the shop expenses, allowing nothing for the master's expenses and time, and no plumber known to the writer ever made any money and kept it and stayed in business without getting from 25 per cent. upwards on contract work, including profits on extras of course.

Another thing, don't worry if some patent-leather plumber seems to be getting all the contract work in sight at cost or near it. He may dazzle your eyes with his new wagon and gilt sign; the travelling men may tell you that Skinner is a hustler; that he runs thirty-six men; that he has the Skylight flats and sixteen tenements in a row; don't let that sort of talk move you a peg. Do what little job work you can get, make your customers your friends, and make it a rule that if you cannot get the cost of work with your living added, to let that job go and try another job. Discount your bills and remember the railroad rule in taking contract work: In all cases of doubt take the safe side. Don't contract a job if you have any doubt whatever about getting your money. Don't imagine the mechanics' lien law will get you your money; it is little more than a bluff. A slippery lawyer and a slight technicality will put you in the position of the fellow that drove the hearse: He was not in it. Finally, the writer invariably goes over his work when it is finished to find out what the job did actually cost him. I believe that plumbers get tangled up, and into the clutches of the sheriff, for the reason that they get half way through a lot of work they are losing money on, and get a lot more at the same price, without knowing, they are meeting their Waterloo when settlements become due.

HEATING BY HOT WATER.

WHEN the quantity of air to be heated per minute has been ascertained, says a writer in the *Plumber and Decorator*, the quantity of pipe that will be necessary to heat the room may be found by the following:

Multiply the excess of temperature of the flow-pipe above that of surrounding air by the difference between the temperature at which the room is purposed to be kept, when at its maximum, and the temperature of the external air, and divide this product by the difference between the temperature of the pipes and the purposed temperature of the room; then, the quotient thus obtained when multiplied by the number of cubic feet of air to be warmed per minute, and this divided by 222 (the number of cubic feet of air raised 1 deg. per minute by 1 ft. of 4 in. pipe) will give the number of feet in length of pipe 4 in. diameter, which will produce the desired effect.

When 3 in. pipes are used, the quantity of pipe required to produce the same effect will, of course, be different. To obtain it, the number of feet of 4 in. pipe obtained by the above rule must be multiplied by 1·33. If 2 in. pipe be used, the quantity of 4 in. pipe must be multiplied by two.

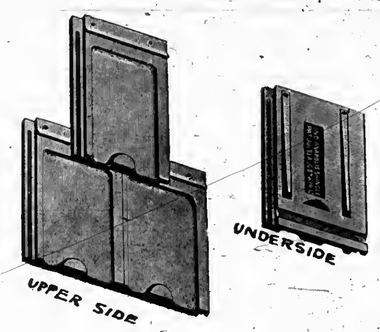
A well known company who make the manufacture of steam and hot water heaters a specialty, now advocate a different method of figuring greenhouses to the one heretofore employed, namely, by exposure; that is, counting in the entire exterior surface, glass, sides and ends. The old method was simply a consideration of the "glass surface" alone, and was liable to error through varying differences in the construction and location of the sides and ends. A table which is conservative and based on a large number of actual trials, shows the amount of square feet of pipe necessary to heat any given number of square feet of exposure to a maximum night temperature of 50 degrees, and also what will be necessary to heat the same amount of exposure to a higher temperature of 60 degrees; this latter being the highest that florists generally want. In computing the total exposure of the greenhouse, one-third of the square feet of the ends and exposed outside wall surface is added to the actual square feet of glass. After finding the number of square feet of piping that will be necessary to heat the house to the given temperature, then it is easy to transfer the square feet of pipe into linear feet of whatever size of pipe may be chosen. —*Master Steam Fitter.*

Mr. Harry G. Powell has opened an office as architect at Stratford, Ont.

MANUFACTURES AND MATERIALS

CLAY FOR SHINGLES.

WE reproduce from the *Clay Worker* cuts of a new shingle tile or "clay shingle" as it is called, which seems to be a great improvement upon the ordinary form in use here. Its general upper surface is depressed, leaving a raised rim wider on one side and grooved to receive a lip on the adjoining tile. The underside of the tile has two ribs, giving strength with lightness, and a groove near the botton edge forming a drip. It is claimed that these tiles so securely lock that the heaviest winds cannot lift them. The size is 7 x 10 inches, with an exposure of 6 x 8



inches. We would be glad to have an expression of opinion from our subscribers who are in the roofing business, or other practical men, as to the merits or otherwise of this tile.

There is little doubt but that a snow and waterproof tile of light weight and great strength would fill a long felt want. Slates are utterly unreliable as a protection against fire, even a moderate heat cracking them and exposing the wooden roof beneath, while wooden shingles are not durable enough for a first-class building, and unless laid on a bed of good mortar more dangerous in case of fire than slates.

ASPHALTE VERSUS TAR AND GRAVEL PAVEMENTS.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—Asphalte pavements are in danger of falling into disrepute, not because asphalte has been found wanting in any property necessary to the making of a good and durable pavement, but owing to a pernicious habit, either the outgrowth of ignorance or carelessness. I refer to the misleading statements to be met with daily in the columns of our newspapers, as furnished to them by corporate bodies and others to the effect "That an asphalte pavement is to be laid on such and such a street," when in reality the pavement is to be constructed of tar and gravel. It is not my intention to go into the respective merits of asphalte versus tar and gravel, as I think it would be an insult to the common sense of your readers to attempt to draw such a comparison, but simply to point out the injustice done to asphalte in general by having such inferior materials as tar and sand dignified by its name.

There are many brands of asphalte on the market, some of them I am sorry to say of an inferior quality; therefore I consider that it is quite sufficient for the genuine article to have to answer for the sins of these brands without being compelled to adopt those of such a primitive and out of date mixture as "tar and gravel."

Yours truly,

JUSTICE.

JOINTS FOR CAST-IRON PIPES.

THE ordinary method in this country for putting cast-iron water or waste pipes together is by a lead-caulked joint. This answers very well when the pipes lie quietly in the ground. But pipes do not lie quietly in all cases. And in houses where hot and cold water is alternately passing through the pipes, expansion and contraction come into play, and the result to the joints is anything but satisfactory. If a steam drip enters one of these pipes, the lead ring forming the packing of the joint will work out upon the pipe within a few months.

Pipes underground are liable to disturbance from a variety of causes. Leakage usually results from any movement of the pipe; with water-pipes these leakages are annoying and costly. If a cast-iron pipe happens to be carrying gas instead of water, the leakage at once becomes costly and dangerous.

The lead-caulked joint is costly, and at the same time difficult to make well in confined locations. In plumbing work it is no uncommon thing to

VOL. IV.—No. IX. TORONTO AND MONTREAL, CANADA, SEPTEMBER, 1891. { PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),

PUBLISHED ON THE THIRD SATURDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

14 King Street West, TORONTO, CANADA.

64 TEMPLE BUILDING, MONTREAL.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

THE Parks and Gardens Committee of the Toronto City Council has succeeded in a period of five or six years in transforming the eastern half of Toronto Island into a delightful park. The sweepings from the city streets, and soil from excavations for new buildings, etc., have been carried to the island on scows and there used to fill up the lagoons. On the land thus "made," young trees have been abundantly planted, and have already attained sufficient growth to afford a certain amount of shade, in addition to what may be obtained beneath the trees of larger growth on the older part of this section of the Island. This Island Park will go far to make good the loss which the citizens have sustained through the short-sightedness of the past, which has left them almost entirely without central parks and squares in the city proper. Island Park is so near at hand, so easily accessible, and so delightfully situated, that its value to the citizens of this and future generations would indeed be difficult to estimate. We presume it is the intention of the Park Commissioner to transplant some of the trees, as at present they stand much too close together. It may also be remarked that full advantage will not be taken of the park until the ferries are compelled to lower their rates.

ARCHITECTS in England have many advantages which their confreres on this side of the water have not. Their annual excursions to historic localities are always full of interest, but this year the Society of Architects has carried out the more ambitious project of an excursion to Belgium. Some forty-one members availed themselves of the trip, and the first excitement consisted in being presented to the King at his palace at Ostend. This was on a Saturday. Sunday and Monday were spent in Bruge—being brim-full of interest. Tuesday was spent in Ghent, Wednesday in Antwerp, Thursday in Malines, or, as it is sometimes called, Mechlin, and thence to Brussels—Friday and Saturday in Brussels, with a hurried run to Louvain. On the Monday, a portion of the party being unable to remain longer, left for home, while the remainder proceeded to Mons. Tuesday was spent in Tournai, Wednesday at Andenarde, Courtrai, on Thursday, and the last day, Friday, at Ypes, leaving in the afternoon for Ostend and thence to England on Saturday. Many of the party spent considerable time in sketching, the results being seen in the architectural journals. The effect of such a trip and in such congenial company, must have been truly inspiring, and cannot but result in great good to those participating.

WE publish elsewhere the proceedings of the first annual meeting of the Province of Quebec Association of Architects. Some 34 out of a membership of about 70 attended, being a very much larger percentage than that recorded of many similar organizations. As will be seen, the whole of the officers were re-elected, with the exception of Mr. Hopkins, who positively declined, when the 1st vice-president, Mr. Berlinquet, was elected to the position. The annual report indicates a most commendable activity on the part of the Council, 21 meetings having been held, with the result that incorporation has been secured, examinations instituted and a scheme for the regulation of competitions formulated. The Association has thus evinced an *esprit du corps* and a vitality worthy of emulation, and if its progress continues at the same ratio, the resultant advance of the profession will be most marked. The reading of professional papers and discussions thereon, which proved of so much interest at the Ontario gatherings, were conspicuous by their absence. We presume, however, that when the Association gathers a little more strength, and now that the weightier matters have been put into shape, the members will have time to prepare papers for future meetings. The remarks of Mr. Berlinquet at the banquet in the evening, in proposing the toast of the Quebec Association, and of the other gentlemen who spoke, should be pondered over by the members of both Associations. The toast of the sister Association in Ontario was happily introduced by Mr. Roy, who gave it due praise as the pioneer organization. Mr. Doran, in responding, expressed the hope that the time was not far distant when a Dominion Association should be formed, with the provincial Associations in affiliation.

OUR ILLUSTRATIONS.

ST. PAUL'S EPISCOPAL CHURCH, GUILD ROOM AND RECTORY, MUSKEGON, MICH.—POST & HOLMES, ARCHITECTS, TORONTO.

The drawings which we illustrate were placed first in a limited competition, the following firms being invited to submit sketches: Post & Holmes, Toronto; Patton & Fisher, Chicago; J. K. Cody, Chicago, and F. S. Allan, Joliette. The buildings are to be built of brown stone, laid in random ashlar work, the upper storey of rectory being in half timbered work. The roofs of church and guild room will be "open timbered." The church will accommodate 600, and the guild room 300. The estimated cost, exclusive of heating and furniture, &c., is $40,000.

RESIDENCE OF MR. W. E. PRICE, DORCHESTER ST., MONTREAL.—A. F. DUNLOP, ARCHITECT.

RESIDENCE FOR MR. THOMAS OLIVER, HAMILTON, ONT.—W. A. EDWARDS, ARCHITECT.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

THE first annual meeting of the above Association took place in the city of Quebec, on Thursday, the 10th inst. There were present: J. W. Hopkins, of Montreal, President, in the chair; F. X. Berlinquet, Quebec, 1st Vice-President; V. Roy, Montreal, 2nd Vice-President; A. C. Hutchison, A. F. Dunlop, A. Raza, A. T. Taylor, M. Perrault, Montreal; J. F. Peachy, Quebec, Councillors; W. E. Doran, Montreal, Treasurer; C. Clift, Montreal, Secretary; H. Staveley, A. H. Larochelle, D. Ouelette, L. C. E. Page, I. G. Bussieres, I. B. Bertrand, Thos. Raymond, G. E. Tanguay, A. J. Pageau, Chas. Baillairgé, E. Dusscault (student associate), R. Le May (student associate), Quebec; R. Findlay, W. H. Hodson, J. Z. Resther, Jos. Haynes, G. De G. Languedoc, E. Z. Gauthier, J. Esinhart, A. H. Lapierre, Theo. Daoust, Jas. Wright, A. Gendron, Montreal.

The minutes of the annual meeting before incorporation and last general meeting were read and confirmed.

The following report from the Council was read:—

ANNUAL REPORT OF THE COUNCIL.

GENTLEMEN,—At our annual meeting of October 10th, 1890, your Council was instructed to procure an Act of Incorporation, also to deal with matters in relation to competitions. On the 30th of December last we succeeded in procuring an Act of Incorporation, a copy of which has been sent to every member of the Association. The Act stipulated that the Council meet within one month and re-organize, forming necessary by-laws, to be ratified at the next annual meeting.

On the 15th and 16th of January your Council met, organized, under the Act, and elected the officers that were elected at the last general meeting. They framed the by-laws and adopted them as sent to each member, and which are now open for amendment and ratification at this meeting.

Since the organization under the Act in regard to matters of competitions, your Council after interviewing the Building Committee of Montreal Board of Trade, succeeded in having a few minor admendments made to the conditions prepared by the Building Committee; nevertheless, as the Building Committee did not accede to the more important items your Council found objectionable, they deemed it desirable to ask the members to refrain from engaging in the competition, and with that view prepared a petition which was signed by about 20 members, a copy of which was sent the Building Committee of Board of Trade. Your Council have prepared a guide for competitions which will be submitted later on at this meeting.

The Act sets forth that a tariff had to be prepared by the Council and sent down to the Lieutenant-Governor. The tariff as prepared will be read to you later. It has been sent to the Lieutenant-Governor, and now awaits his sanction.

The Board of Examiners elected at the meeting of January last consists of Messrs. Berlinquet and Baillarge, of Quebec, and Roy, Thomas and Taylor, of Montreal. They have framed programme of subjects for examinations, which have been printed. Examinations were held by the Board of Examiners last 30th and 31st of July. Two students went up for matriculation and one for the final examinations. Those for matriculation succeeded in passing; the one for registration was not equally successful. The officiating members of the Board were Messrs. Thomas, Roy and Taylor.

The Council has held 21 meetings. The attendence has been as follows:—J. W. Hopkins, 18; V. Roy, 17; A. Hutchison, 17; A. F. Dunlop, 19; M. Perrault, 4; A. Raza, 14; A. F. Taylor, 18; W. E. Doran, 13; C. Clift, 20. Quebec members—F. X. Berlinquet, 15; J. F. Peachy, 2.

The Council have engaged rooms for the use of the members of the Association, one large room about 35' x 160", and a room for the Council adjoining. There is a large fire-proof vault and store room and all the necessary conveniences. The rooms are situated on the second floor at 186 St. James St., Montreal, and have been furnished with tables, chairs, etc. The lease is for three years from May next, but we have the option of leaving next May, provided the Council give the required three months notice. The rental is $200; the proprietor paying for cleaning, water, and all ordinary taxes. The rooms were formally opened on August 4th last. The Council have not yet succeeded in furnishing a library, but hope this will soon be accomplished, as also the delivering of lectures and the forming of classes for the students.

There are seventy members on the roll and 41 students. There has been paid into the Association by its members and students the sum of $2,280; and there is still the sum of $400 owing by the members and students. Your Council last January when they organized, found it necessary to raise the registration fee to enable them to meet the obligations incurred in procuring the Act, and yet later at the general meeting of the Association last May, it was again found necessary to assess each member the sum of $5.00 additional, thus making the registration fee $25.00. We are thankful to say that the members acceded to the request with alacrity, whereby your Council were enabled to meet all obligations, leaving a good balance in the Treasurer's hands. The Council take this opportunity of thanking the members for the handsome manner in which they have responded to all calls made upon them. All respectfully submitted on behalf of the Council.

J. W. HOPKINS, President.
CHRS. CLIFT, Secretary.

TREASURER'S REPORT.

Receipts.

Monies received by members fees, etc.,	$2,287.83

Expenditure.

Paid out for Act of Incorporation, printing, furnishing of rooms, expenses of delegations to Quebec, rental, etc.,	$1,814.49
By balance in bank	473.34
	$2,287.83

Auditors { J. NELSON, CHAS. BAILLARGE. (Sgd.) W. E. DORAN, Treasurer.

It was moved by Mr. Staveley, and seconded by Mr. J. Z. Resther, that the report of the Council with the audited Treasurer's report be received and adopted, and that they be printed and a copy sent to each member. Carried.

The Secretary was instructed to notify each member in arrears according to the Act and by-laws.

The by-laws were then read, and after being slightly amended, it was moved by Mr. Clift and seconded by Mr. Raza, that as now amended they be finally adopted, translated by the committee already appointed, then printed in proper form with the Act and a list of the members and students belonging to the Association, a copy sent to each member and student associate.

The Secretary then read the suggestions for the conduct of architectural competitions as adopted by the Council, which were unanimously adopted, and the Secretary was instructed to have it translated and printed and a copy sent to each member.

The election of officers, etc., was then proceeded with.

The Chairman appointed Mr. H. Staveley and Mr. J. Z. Resther to act as scrutineers.

The whole of the officers and Council were then elected by ballot, the scrutineers reporting the following officers duly elected to fill their respective offices for the ensuing year:

President, F. X. Berlinquet, Quebec; 1st Vice-President, V. Roy, Montreal; 2nd Vice-President, J. Nelson, Montreal; Treasurer, W. E. Doran, Montreal; Secretary, C. Clift, Montreal; Six members of Council: A. C. Hutchison, Montreal; A. F. Dunlop, Montreal; A. T. Taylor, Montreal; A. Raza, Montreal; M. Perrault, Montreal; J. F. Peachy, Quebec; Auditors, J. W. Hopkins, Montreal; Chas. Baillargé, Quebec.

Mr. Hopkins was asked by a large number of members to stand as President for another year, but he begged the members not to vote for him as he could not accept the honor for another year, and sincerely hoped they would elect the 1st Vice-President to the presidency, whereupon Mr. Berlinquet was elected by an unanimous vote.

A vote of thanks was tendered to the scrutineers.

It was moved by Mr. V. Roy, and seconded by Mr. Berlinquet, that Mr. Hopkins be tendered the most heartfelt thanks of the members of this Association for the able and efficient manner in which he had filled the position of President since the formation of our Association. Unanimously carried.

It was moved by Mr. J. Z. Resther, and seconded by Mr. Page, that the thanks of the members be tendered Mr. Clift for the services rendered this Association since its formation, also that it be accompanied with a cheque for $150 as a present. Unanimously carried.

It was moved by Mr. Ouelette, and seconded by Mr. J. Z. Resther, that a vote of thanks be given the Council for their efficient services. Unanimously carried.

At this stage Mr. Hopkins conducted the newly elected President to the chair.

It was decided to advertise in a Quebec paper when matters affecting the Quebec members and students came up.

It was moved by Mr. Doran, and seconded by Mr. Raza, that the next annual meeting be held in Montreal on date according to the by-laws. Carried.

It was decided that the Council prepare a form of agreement and conditions of contract for the use of all members.

There being no further business, the meeting closed.

THE BANQUET.

In the evening the members of the Association assembled at a banquet in the Florence Hotel, at which, as will be observed from the annexed report of the proceedings, a most enjoyable and profitable time was spent.

The following gentlemen sent letters expressing regret at their inability to attend the banquet: Messrs. Arnoldi, Ottawa, W. A. Langton, Toronto, Edmund Burke, Toronto, E. E. Taché, Assistant Commissioner of Crown Lands, Quebec, and Messrs. Charest, Trudel and St. Michel, Quebec.

The toast of the Queen was proposed by the President, Mr. Berlinquet, and received with enthusiasm, all present joining in singing "God Save the Queen."

In proposing the second toast, that of the Province of Quebec Association of Architects, Mr. Berlinquet said:

GENTLEMEN,—I have now to propose the toast of the Association of Architects of the Province of Quebec. This toast will, I have no doubt, be drunk with pleasure by all present. This Association has in view an object of which we are all well aware, and one which should commend itself to everybody. It has for object the strengthening of the profession, and the rendering of its members more capable in the performance of their duties. Union is strength. Each member of this Association of Architects may be compared to a stone forming part of a structure; and as in a structure each stone has its allotted place and object, and all the stones being put together with harmony form something grand and imposing, so each member of this Association

"CANADIAN ARCHITECT AND BUILDER" STUDENTS' COMPETITION.

WITH the object of promoting a feeling of friendly emulation on the part of students in the offices of members of the Province of Quebec and Ontario Associations of Architects which should result in improving the skill of the young men thus engaged, the publisher of the CANADIAN ARCHITECT AND BUILDER invites competitive designs for a suburban cottage to be occupied by a young man doing business daily in the city, owning the lot, possessing $2,000 in cash and having an income of $1,400 per annum.

The cottage is to be erected on an inside town lot having a frontage of 75 feet, a depth of 150 feet, and situated on the west side of the street.

There is required in the way of accommodation a parlor, small library, dining room and kitchen; cellar, suitable for heating apparatus and storage of fruit and vegetables.

On the first floor there are to be four bedrooms and bathroom.

The attic is to contain a servant's bedroom and store room.

The materials to be used shall be brick on a stone foundation.

There is no sewerage or water supply systems in the town, and the owner will have to dispose of all waste in the most sanitary manner, avoiding contamination of the soil from which he has to draw his supply of water.

Competitors are required to submit plans of the various floors, two elevations, unless accompanied by a perspective, when one will do

Drawings must be made on sheets of heavy white paper or bristol board, 14 x 20 inches in size, and must be drawn sufficiently coarse to allow of their being reduced to one-half the above size. Drawings must be made in *firm, strong lines*, with *pen* and *black* ink. No color or brush work will be allowed. Each drawing must be marked with the *nom de plume* of its author, and the author's name, *nom de plume* and full address must accompany each drawing sent in. Competitors must also give the names of the architects in whose offices they are employed.

Drawings must reach the office of the CANADIAN ARCHITECT AND BUILDER, 14 King St. west, Toronto, not later than the 5th day of November next.

The right is reserved of publishing any design sent in. All drawings will be returned to the authors within a reasonable time after the competition is decided.

The first premium will be $15; second, $5; third, one year's subscription to the CANADIAN ARCHITECT AND BUILDER. A premium of $5 will be given for the best perspective sent in. The decision as to the respective merits of the designs submitted will be made by Mr. Thos. Fuller, chief architect, Department of Public Works, Ottawa, which decision will be final.

This competition is confined to students practising in the offices of members of the Province of Quebec and Ontario Associations of Architects.

GLAZING COLORS.

GLAZING is a term which has probably been borrowed from the potter's art of coating the ware with a transparent vitreous substance.

The house-painter uses the word glaze in speaking of the setting of window-panes, and the word is used also by other trades when speaking of a finish that adds luster.

Glassy, transparent, is the correct meaning, therefore glazing colors are those possessing but little body, or covering power, and which are employed when richness and brilliancy are desired.

Body colors may be rendered transparent or partially so by using but little color to a large proportion of vehicle; but such glazing is of no value except to landscape painters, and not much to them.

There is no difficulty in producing a perfect glazing coat, when the painter knows how to prepare the foundation colors.

The self-taught painter, supposing that all colors are used the same, may worry over his carmine or yellow lake and wonder why they will not cover, and he may give up in despair; but the regular vehicle painter, knowing what is demanded, proceeds with a glaze with as little concern as he would for a body color.

Any body color which is to be used as the color proper should be fine, clean, and laid on perfectly smooth. This being the practice in good shops, glazing is merely the extra work of laying two or more coats of transparent color.

The glaze may be put on thin and but one coat given, which is practiced when it is desired to impart brilliancy to the under coat. Brilliant vermillion is produced by a thin glaze of carmine over vermillion, and the same method may be adopted with the yellow and green lakes.

The common practice is to prepare the ground color so that it will closely match the tone of glazing color as it appears when mixed or "wet up," for every color is slightly deeper in tone when wet or mixed in oil or varnish; but the glazing colors are capable of a wider application, for they may be painted over grounds wholly opposite in color. Thus carmine may be glazed over lead color, black, and also over white, yellow, pale green, verdigris, blue, purple, violet and yellow lake; verdigris and ultramarine blue may be glazed over about the same range of colors, but when so used they are better adapted to narrow spaces, striping ornamental and pictorial work.

THE TORONTO ARCHITECTURAL SKETCH CLUB.

MR. Frank Darling has offered a prize of books to the value of $10, for the best set of measured working drawings of the front porch of the Canada Co. Building, corner of King and Frederick streets.

The following drawings are to be submitted: Elevation, section and plan, inch scale; sections of mouldings, full size; elevation, section and plan of caps, showing front and diagonal views of volutes, full size. All drawings to be made in black ink on white paper, no brush work being allowed. Neatness and general arrangement of the drawings will be taken into consideration.

Drawings to be submitted under *nom de plume*, the author of the work enclosing his real name in a sealed envelope. Members of the Sketch Club only are permitted to compete.

The drawings to be delivered to Mr. Frank Darling, *Mail* Building, not later than Monday, Nov. 2nd.

STAINING OAK BROWN.

A correspondent asks for a receipe for staining oak so as to match old brown oak. Wood is stained by the application of the ordinary liquid dyes employed for wool or cotton. They sink deeper into the wood when they are applied hot. A decoction of oak bark produces brown of various shades, according to the quantity employed; so does an infusion or decoction of walnut peels. The above information is from Cooley's Practical Cyclopædia of Practical Receipts. We have been told that Condy's Fluid, more or less diluted with water, will stain wood brown. If a very dark brown is required, it may be necessary to introduce a little black. In the supplement to the *Scientific American*, the following instructions are given for dyeing oak black, so as to resemble ebony; and, of course, lighter shades of black can be produced at will by employing more water than is prescribed: Immerse the wood for 48 hours in a hot saturated solution of alum; and then brush it over with a logwood decoction as follows:—Boil one part of the best logwood with ten parts of water, filter through linen, and evaporate at a gentle heat until the volume is reduced one-half. To every quart of this add from 10 to 15 drops of a saturated solution of indigo. After applying this dye to the wood, rub the latter with a saturated and filtered solution of verdegris in hot concentrated acetic acid, and repeat the operation until a black of the desired intensity is obtained.

PERSONAL.

Mr. D. W. Ouellet, architect, will leave Quebec on the 20th inst., for a visit of three months to the principal cities of Europe.

The senior partner of the firm of Langley & Burke, architects, Toronto, has just returned from a visit to the Canadian northwest.

Mr. J. B. Reid, architect, Kingston, Ont., has been visiting Europe. Mr. Arthur Ellis has been in charge of his practice during his absence.

Mr. F. X. Berlinquet, architect, Quebec, has just returned from an extended tour in Europe, and in consequence is looking and feeling greatly improved in health.

Mr. W. E. Doran, of Montreal, after attending the Convention of the Province of Quebec Association of Architects at Quebec, returned home via Boston and St. John, N. B.

Mr. C. H. Bishop, Superintendent of Public School Buildings, Toronto, accompanied by Mrs. Bishop, sails from New York to-day (the 19th inst.), for Europe, where he will spend some five or six weeks in visiting points of interest in England, Scotland and France. He will doubtless bring back with him much information which may be utilized to advantage in the construction of school buildings in the future.

PROCESS OF MAKING SLAG BRICKS AT KOENIGSHUETTE, IN SILESIA.

THE slag is run into a large ladle containing fine coke dust, about one and one-half inches thick. The ladle is then run upon wheels to where the bricks are to be made. The slag and coke dust are then mixed together with a curved iron or rabble. The gas generated by the coke is worked up with the liquid slag the product being a doughy sponge-like substance, full of holes, exceedingly light and possessing sufficient elasticity in the walls of the cells to meet the contraction and thus prevent fracture. This material when pressed into a brick does not require annealing. The bricks possess great strength with very little weight, and are capital non-conductors of heat and sound.

has his special duties to perform in connection therewith, and all united together cannot but make a strong and enduring Association which must be productive of good results in the future. The art of architecture is based on Nature, and the grandest and most perfect specimens of her handiwork are man and woman; and when men are united together for any good object, the strength begotten of their union enables them to build up works of beauty and endurance. I do not hesitate to say that such a result awaits our combined efforts. I now propose the toast of the "Province of Quebec Association of Architects."

Mr. Hopkins, of Montreal, in response to this toast, said:

Mr. President and Gentlemen,—I feel very diffident in rising to return thanks to the Association. Of course, having been the first president, I ought to know something of the progress of this society, and I presume I do. When we last met to-day I said a few words. As you know, I am not a man of many words, but I expressed to you how happy I was to be connected with the Association, and how gratified I was to find that during the first year so much progress had been made. I have not the slightest doubt that the new president and officers, most of whom have been re-elected, and therefore, metaphorically speaking, "know the ropes"—I have not the slightest doubt that they will be able, with the aid of a good rudder, which I am confident they will secure in some way or other, to steer the ship of our Association in its proper course for another year. Possibly, it having been our first year, the machinery may at one time have run a little loose and at another, a little stiff; but with the experience already gained, and with the hearty co-operation which, I feel assured, the members outside of the Council will give to it, another year will find us in a more prosperous condition than we are at present. I must avail myself of this opportunity to thank you in the most sincere manner for the honor which you intended to bestow upon me to-day; and I only regret that it was not in my power to accept it. I am sure my successor will prove an improvement—the second edition being always better than the first, and the latest edition containing the most news—he is younger in years and has had experience both in this city and in Montreal, both of which cities will participate in the advantages to be derived from the meetings of the Association alternately (applause).

Mr. A. F. Dunlop, in reply, said:

Mr. President and Gentlemen:—It gives me great pleasure to be among so many of my honoured confreres this evening—the second annual meeting of our Association. Two years ago I had not thought it possible to form this Association. Public opinion was against us; in fact, most of the present members felt how hopeless such an undertaking would be. But this meeting proves that nothing is too great to accomplish, as we have not only formed the Association, but its future prosperity is also assured. There is, however, one vital and all important point, on which I wish to say a few words. The general public are not thoroughly well informed as to the object of our Association. They have an idea that we are formed into a close profession for the purpose of preventing anyone else from being an architect, and that we intend to raise the standard of our charges. Gentlemen, this is a base slander on our good intentions. We are formed into this Association for the advancement of architecture, for the better serving of our clients, and for the better education of our students; also for the establishment of schools and classes of architecture, and for the purpose of making every architect of the future a competent one, and one whom the public may employ with confidence. Would you employ a doctor who had simply been a druggist for a few months to attend your sick child or parent? Would you employ a notary or a lawyer who had only been in a bailiff's office for a limited period to draft your deeds? Then why employ a man who calls himself an architect—a man without training, and one who would put in 12" timber where it requires 24", and *vice versa*. Is it not a fact that the proper construction of a building is as important to life and safety as the employment of a proper doctor? You jeopardize a life with a poor doctor, and you jeopardize a hundred lives with a poor architect.—It is the architect on whom the public must rely for the proper construction of their buildings. Should not the architect be thoroughly practical, and know how to use material with economy? Should he not know the exact requirements of the art of architecture in all its branches to enable him to satisfy the wants of the public? and as for sanitary requirements, the architect has far more to do with the health and long life of the world's great family than the physician, and is in a great degree answerable for the ailments and early deaths of many. How can all this knowledge be acquired unless we join together and establish schools, classes of architecture, libraries in our colleges for our students? Why should not every architect of the present and future be on the same footing, as regards qualification, as a doctor, lawyer, notary, or druggist; and why should not the public be guaranteed that he is so? I claim that an architect has as great a mission to perform, and without training and education our public and private buildings must be at best fire traps, badly constructed, badly ventilated, badly designed, and a disgrace to our country, while on the other hand, our educated and trained students would make architects of whom the world would be proud, and it would be an honour to belong to such a profession. An architect would then be looked up to with respect and confidence, and not as now, in many cases be regarded with suspicion and doubt. Our ranks would be filled with qualified men who would say with Shakespeare:—

> "When we mean to build,
> We first survey the plat, then draw the model;
> And, when we see the figure of the house,
> Then must we rate the course of erection
> Which, if we find outweighs ability,
> What do we then but draw anew the model
> In fewer offices; or at least, desist
> To build at all? Much more in this great work
> (Which is almost to pluck a kingdom down,
> And set up another), should we survey
> The plat, of situation, and the model;
> Consent upon a sure foundation,
> Question surveyors, and know our own estate
> How able such a work to undergo;
> To weigh against his opposite; or else
> We fortify on paper and in figures.
> Using the names of men instead of men:
> Like one that draws the model of a house
> Beyond his power to build it; who, half through
> Gives o'er, and leaves his part created cost
> A naked subject to the weeping clouds
> And waste for chirlish winter's tyranny."

Mr. Hutchison being called upon, said:

I am of course glad to take part in the first annual meeting of our Association. During the past year we have tried to lay the foundations of our Association like good architects; and while the foundation that we have in the Act is not, perhaps, the very best we could have had, like good builders, we must make the best of it. A great part of the work of the past year has been, and probably the work for two or three years to come will be, merely laying the foundations of our Association. The older members of the profession, like myself, who have borne the brunt and heat of the day in times past, will, perhaps, get no further than laying the foundations. We all know, however, that the most important part of a building is the foundation; and while it is lost to sight, and there is nothing beautiful about it, still on the excellence of the workmanship depends the firmness of the building; and I hope that we will be able to lay a foundation so broad and deep that this will be a lasting Association. (Applause.) I hope, Mr. President, to see a superstructure raised upon the foundation which we are now laying; and I have great hopes in that superstructure being something good, from the fact of the steps we have taken to bring a proper class of persons into the profession. I am very much pleased with the late examinations for matriculation held in Montreal, I am pleased to see that so high a standard is required to enter the profession; and to the faithful performance of the duties of the board of examiners I attach great importance in the making of our Association a success. I trust that they will be very strict in the examinations for entry into the profession. It is, I think the only means of raising our profession to a high level; and I hope the Board of Examiners will ever bear that in mind. I am beginning to feel that I am getting old, and I will in a few years perhaps be out of active service. It is my earnest wish that the young men rising up will be an honor to the profession. I am looking forward with a great deal of hope to be able to see during this coming winter and succeeding winters something done towards that end by the formation of classes or the delivery of lectures to help our young men on in their studies. Of course, you are all aware that heretofore the study of architecture in any of our offices has been somewhat of a farce. I do not think there is an office in the Province of Quebec where there has been a systematic teaching of architecture. For my own part I have always refused to take young men, because I knew I had no time to devote to teaching them. Now, I hope that our Association, having secured a home of its own, will establish during this winter and succeeding winters, classes in which a proper course of training will be carried out. I think feelingly on this subject, Mr. President, from the fact that all my own studies had to be carried out under very great difficulties. I am sure I studied for months at some subjects, when perhaps a lecture or two would have made them clear to me and saved me very great trouble. By putting facilities in the way of our young men we ought to raise up a better class of men than the old ones; and in this direction I trust that our Association will attain great success. (Applause.)

The toast of the sister Association of the Province of Ontario was proposed in a very neat speech by the Vice-President, Mr. Roy, who, in the course of his remarks, said: I would like to propose the toast of the sister Association of the Province of Ontario. This toast will no doubt be drunk heartily for several reasons. The Association of the Architects of the Province of Ontario is the first Association organized in Canada. We are the second; but we have had their work before us as an example to follow. Seeing the success which they had with their Association, we in the Province of Quebec failed to see why the same success should not await our efforts in the same direction. I am happy to see that even they have recognized the great success which we have had in Parliament and elsewhere in the short time which has elapsed since we set about our self-appointed task. The realization of their hopes was longer deferred than ours, and it took them more time to reach the point which we have attained to-day than has been necessary with us. The Association of Ontario has done a great deal for the advancement of the art of architecture; and thus have they not only

benefitted the Association but also the public at large. The public in Ontario feel it. The public feel that when they take an architect belonging to the Association, they have an architect possessed of the ability requisite for the proper carrying out of the work which he undertakes. Gentlemen, I drink this toast with the greatest pleasure, and I know that you do likewise.

Mr. Doran was called upon to respond to this toast, and said:

Mr. President and Gentlemen,—I suppose I must for the moment imagine that I am a foreigner—at least foreign to this province. I must at the outset express my regret that there is no genuine native born Ontario man here to speak for them, but I suppose I must become naturalized and for the time being consider myself as an Ontario member. When I was first asked to respond to this toast the question arose why I should be selected, instead of any other member of the Association, to denationalize myself from the Province of Quebec and become, for the time being, the representative of the sister Association of the Province of Ontario, and that question I have not been able to solve. Well, to proceed, on the part of the Ontario Association I return the most sincere thanks for the manner in which this toast has been received; and as art really knows no nationality, much more it may be said that art in Canada, particularly that of architecture, should know no nationality, that it should be one broad Canadian work. We hope the time is not far distant when it will be the Association of Architects of the Dominion of Canada (Applause), and when the Provincial Associations will be small branches (the same as to-day we have the local branches of Montreal and Quebec of the Provincial Association) of that greater Association of the Dominion. In this manner the prosperity and growth of the Dominion may be advanced, because there is no surer way, no more eloquent way, of telling in the most silent manner possible of the greatness of a country than by pointing to its architectural monuments. When the songs of the poet will be forgotten, the monuments of stone raised by a people shall pass down to future ages and testify to the grandeur and greatness of their country, as do those majestic monuments of ancient Greece to-day. The magnitude of examples of architecture should testify to the greatness of our country, and the stamp of originality which we hope will be placed on our buildings, and which we hope our Association will tend to foster, may prove that Canada is a nation, that it is a country fair and free, a country of which we may all be proud. (Applause.) It is to be hoped, gentlemen, that the Association of the broad Dominion will soon take the place of the Provincial Associations, and carry onward and forward the good work which has been begun by the Provincial Associations. Mr. Hutchison spoke of us as building the foundations. Let us hope then that the foundations which we are building may be the foundations of a vast arch which will spring over all this country, and unite not in bands of iron but in bands of stone, if I may use the expression, the whole country. (Applause.) Gentlemen, I think I cannot do better before resuming my seat, than to propose the toast of "Canada, Our Country,"—the country of which we may justly feel proud; and I will call upon our friend Mr. Baillargé to respond to this toast in the fitting terms which he so well knows how to use.

Mr. Baillargé responded briefly to this toast, saying: I must say that you have made a very poor selection in calling upon me to respond to this toast. Of course we are all proud of Canada, though it would appear just now that our American cousins are doubtful of the propriety of annexing us, for fear they should be led into bad ways. I am glad to see that in our by-laws we have taken good care to exclude all kinds of boodling, still it is so difficult to make a dollar, that perhaps you would like to know the way the miller advised his sons to manage when they could not make a dollar honestly, and with your permission I will give you "The Miller."

Mr. Baillargé then entertained the banqueters with the rendering of a humorous song entitled "The Miller."

The toast of the "Press" was proposed by Mr. Clift in a few well chosen words, and responded to by Mr. J. B. Mortimer, who was followed by Mr. Haynes.

The toast to the retiring President, Mr. Hopkins, proposed by Mr. Roy, was received enthusiastically, all joining in the chorus, "For he's a Jolly Good Fellow."

Mr. Hopkins, responding, said: Mr. President and Gentlemen:—I thought you would have got pretty near tired of hearing my speeches, which amount to noise and nothing else. My old friend Mr. Roy, I know, spoke feelingly in proposing my health, because we have been friends for many years; and I assure you that I feel very grateful and very much indebted to you all for the manner in which you have accepted this toast. I hope that at any time that my assistance can be of the slighest value you will not fail to call upon me. You have almost overpowered me with the enthusiasm of your demonstration; and I can only hope that those who succeed me will obtain—I know they will merit it—the same kind expression of feeling which you have shown towards me.

The toast of "The Retiring Council," proposed by Mr. Larochelle, was responded to by Mr. Piché, who said:

Mr. President,—Mr. Larochelle has proposed the health of the Council which guided the affairs of our Association during the past year. I must say that I have not participated in the carrying out of their work as much as I should like to have done. I cannot but say that the work which has been done, particularly in Montreal, merits high praise; and if the Association stands on a sure and solid footing to-day, it is owing in large part to the gentlemen belonging to Montreal. We have started out well, and let us continue to go forward with a firm step, confident that we are doing good conscientious work, which will have its effect not only among ourselves but also among the public, who well know how to appreciate it. (Applause.)

Mr. Ouellet followed with a few brief remarks expressive of his gratification at the thorough appreciation by the members in general of the efforts put forth by the Council of last year for the advancement of the interests of the Association.

Mr. Clift called for a toast to the newly elected President, Mr. Berlinquet, saying that he felt confident that Mr. Berlinquet would be an honor and an ornament to the Association, and would do full justice to the position which he was called upon to fill.

Mr. Berlinquet, replying, said that it was but right and fitting to compliment those who had acquitted themselves of their duties in a praiseworthy manner; but it was rather premature to bestow praise upon one whose work was not really commenced. He assured the Association that he would do his utmost, and was prepared to make any sacrifice, to fulfill the duties which should devolve upon him in the onerous position to which they had raised him.

The health of "The Ladies" was then drank with gusto, and Mr. Gauthier answered for them in a most happy manner.

In the course of the evening the banquetters were entertained by the rendering of several fine songs by Messrs. Gendron, Roy and Pageau.

The newly elected Council held its first meeting at the Florence Hotel on the 12th inst., and after having disposed of some routine business, accepted the invitation of the President, Mr. Berlinquet, and Mr. Peachy, to enjoy a drive about the city.

EXAMINATION PAPERS, ONTARIO AND QUEBEC ASSOCIATIONS OF ARCHITECTS.

ONTARIO ASSOCIATION PRELIMINARY EXAMINATION.

CANDIDATES, except such as have matriculated in arts in any university in Her Majesty's dominions, or in the Ontario School of Practical Science, must have passed the examination of the second form of a High School or Collegiate Institute; or, as an alternative, must have passed the entrance examination to a High School or Collegiate Institute, and submit to an examination in Mathematics, and either French or German equivalent to that of the second form of a High School or Collegiate Institute.

The first time of sending in his name as a candidate for examination, the student shall send also a certificate of his status with reference to the Preliminary Examination.

ONTARIO ASSOCIATION FIRST INTERMEDIATE EXAMINATION.

Every candidate must, at least one month prior to the date fixed for the examination, send to the Registrar the following drawings, which must be certified by his principal to be his own work:

Four sheets of drawings, one of each of the four orders of Greek architecture; One sheet of the mouldings and ornaments of the orders, drawn to a larger scale; (Each sheet to be of the size of a half sheet of Whatman's Double Elephant paper, *i. e.*, 20 in. by 26 in.)

The subjects for examination will be:—

ELEMENTS OF CONSTRUCTION.—Text Book: Mitchell's Building Construction, Part I.

MATHEMATICS.—Euclid; Books I., II. and III.; Plane Trigonometry: Including the solution of plane triangles; Algebra: Including quadratic equations.

TECHNICAL TERMS.—A knowledge of the terms necessary to understand the descriptions of a monumental building and its parts.

HISTORY OF ARCHITECTURE.—An outline only will be required, such as may be learned from reading such works as Rosengarten's Architectural Styles.

ONTARIO ASSOCIATION SECOND INTERMEDIATE EXAMINATION.

Every candidate must at least one month prior to the date fixed for the examination, send to the Registrar the following drawings, which must be certified by his principal to be his own work:—

One sheet of Romanesque architecture; Two sheets of Gothic architecture; One sheet of drawings measured from existing examples; One sheet of constructional details. (Each sheet to be of the size of a half sheet of Whatman's Double Elephant paper, *i. e.*, 20 in. by 26 in.)

The subjects for examination will be:—

STATICS, GRAPHICAL AND ANALYTICAL.

STRENGTH OF MATERIALS.—Text book for both the above heads: Lessons in Applied Mechanics, by Cotterill & Slade; Part II.

STRUCTURAL IRON WORK.—The candidate will be required to draw details of the forms of iron construction in use in ordinary practice, viz., the construction of columns and girders, and the framing of beams and trusses.

HISTORY OF ARCHITECTURE.—The candidate will be expected to have a knowledge of the development of architecture and the characteristics of the different styles; Text book: Fergusson's History of Architecture; Handbooks recommended: Parker's Introduction to Gothic Architecture; Bloxam's Gothic Architecture; Rickman's Gothic Architecture.

ONTARIO ASSOCIATION FINAL EXAMINATION.

Every candidate must, at least one month prior to the date fixed for the examination, send to the Registrar a perspective drawing which must be

certified to be his own work. Drawing to be on a sheet of paper, 20 in. by 27 in., and not mounted on cardboard.

The subjects for the final examination will be :—

HISTORY OF ARCHITECTURE.—The leading characteristics, including mouldings, features and ornaments of all styles; and special characteristics, with mouldings, features and ornaments in detail, of any one style or period the candidate may select.

DESIGN.—As illustrated by drawings for a building of moderate dimensions, from particulars given, with details of construction and ornament and with specifications.

NATURE AND PROPERTIES OF MATERIALS.—Limes, cements, stones, bricks, timber.

FOUNDATIONS.—Text book: Foundations, by Geo. T. Powell.

ARCHITECTURAL JURISPRUDENCE.—Text book: The Law Relating to Civil Engineers, Architects and Contractors, by Macassey & Strahan.

PRACTICAL KNOWLEDGE OF BUILDING TRADES.—Sufficient for the purposes of ordinary building

STRENGTH OF MATERIALS.—Designing structures of an ordinary kind from data, with computation of the strains involved.

HEATING AND VENTILATION.—Text book: Ventilation and Heating, by John S. Billings.

SANITARY SCIENCE.—Text books: Gerhard's House Drainage; Bayles' House Drainage and Water Supply.

QUEBEC ASSOCIATION PROGRAMME OF MATRICULATION EXAMINATION FOR PUPILS.

1. English or French Composition. (A subject to be chosen at the time.)
2. Arithmetic, up to and including fractions.
3. Mensuration of Surfaces and Solids.
4. Algebra.—Simple Equations.
5. Elements of Geometry and 1st and 2nd Books of Euclid.
6. Freehand Drawing (copy to be given.)
7. Linear Drawing—geometrical (Do.)

QUEBEC ASSOCIATION PROGRAMME OF EXAMINATION FOR REGISTRATION AS ARCHITECT.

LISTS OF SUBJECTS, &C.—Preliminary drawings to be sent in previously, and prepared during pupilage, or otherwise, and to be entirely the work of the candidates.

(*a*) Measured drawings of an existing building, for example the chapter house of Christ Church Cathedral, Montreal, or the newly erected side chapel of the Basilica at Quebec to ½" scale with mouldings and ornament ¼ full size.

(*b*) An original design of a detached private residence, with complete plans, sections, elevations and details, colored to show materials, and one perspective view drawn by rule, together with complete specifications for the several works and materials required for the carrying out of said design, and a detailed estimate of cost, which must not be less than $15,000; scale to be not less than ⅛th inch to 1 ft.

(*c*) An essay on the history and characteristics of any one style of architecture to be selected by the candidate, giving fullest particulars, illustrated by sketches, and to contain at least 1,000 words.

WRITTEN, GRAPHIC AND ORAL EXAMINATION.

ART SECTION.—(*a*) The orders of Greek and Roman Architecture, their origin, development and application; with sketches.

(*b*) The several varieties of classic ornament.

(*c*) The development of the different periods of French or English Gothic, commencing with the Norman.

(*d*) The characteristic mouldings and ornament of each period.

SCIENCE SECTION.—(*a*) The nature, qualities and defects of ordinary building materials, such as stone, brick, timber metals, etc.

(*b*) The nature of soils and foundations.

(*c*) The calculation of strengths of materials and resistances from data and formulæ given.

(*d*) The elementary principles of construction.

(*e*) Hygene, drainage, and sanitation of buildings.

(*f*) Architectural jurisprudence.

(*g*) Heating, ventilation and acoustics.

BOOKS RECOMMENDED.

ART SECTION.—Fergusson's History of Architecture; Fergusson's Handbook of Architecture; Viollet-le-Duc Dictionaire d'Architecture, Stuart & Revett's Antiquities of Athens; Sir William Chambers' Civil Architecture; Gwilt's Encyclopædia of Architecture, (1888 edition); Gailhabaud's l'Arch tecture du V. au XVII. Siècle; Parker's Introduction to Gothic Architecture; Rickman's Gothic Architecture, Brandon's Analysis of Gothic Architecture.

SCIENCE SECTION.—Notes on Building Construction—South Kensington series; Dobson's Rudiments of the Art of Building; Dobson's Foundation and Concrete Works; Tredgold's Elementary Principles of Carpentry; Baillairge's Stereometricon; Rankin's Manual of Applied Mechanics and Civil Engineering; Park's Manual of Hygiene, and Works by Latham, Putnum, Bailey-Denton, Hellyer, &c.; Civil Code of the Province of Quebec; Gwilt's Encyclopædia of Architecture (1888 edition), etc., etc.

The announcement is made in the advertisement of the Toronto Pressed Brick Co. that the Company's office and show rooms have been removed from Adelaide street east to No. 139 Yonge street. It is gratifying to be told that the necessity for enlarged space consequent upon the growth of the business has rendered this removal to larger premises necessary.

MANUFACTURES AND MATERIALS

COLORING AND ENAMELING FACING BRICKS.

WHEN *coloring white burning clay*, for 100 parts of material are required, according to the behavior of the basis material :—

COLOR DESIRED.	OXIDE USED.	PER CENT. OF OXIDE USED.
For dark green	Chromic oxide	0.010 to 1.50 per cent.
" pale green	Chromic oxide	0.008 " 0.25 "
" bluish green	Chromic and cobaltic oxide	0.006 " 0.25 "
" deeper blue green	Chromic and cobaltic oxide	0.25 " 0.50 "
" olive green	Cobaltic and nickel oxide	1.200
" pale blue	Cobaltic oxide	0.005 " 0.50
" dark blue	Cobaltic oxide	0.05 " 0.900
" medium to deep yellow	Nickel oxide	0.200 " 0.900
" brown	Antimony oxide or uranic oxide	0.500 " 0.730
" brown	Ferric oxide	0.150 " 6.17
" black brown	Chromic ferric and cobaltic oxides, or manganese with or without uranium.	up to

For *glaze coloring*, 1.5 to 20 per cent. more of coloring matter will be required in proportion to the depth of the respective tone and the developing capacity the of coloring power of the respective oxides, as well as the height of the burning temperature. The many-sidedness of the subject is shown by the following compilation, there being considerable variation in the coloration, especially according to the more oxidizing or more reducing nature of the flame.

	May also turn out.	Should yield according to the quantity used.
Ferric oxide	Yellow, brownish, medium brown-red-brown, orange-red, blood-red, violet brown-red.	Yellow or brown.
Cobaltic oxide	Bluish, water-blue, sky-blue, fiery-blue, black-blue.	Blue
Chromic oxide	Pure yellow, medium deep, inclining yellow, to copper-brown with yellow reflection, greenish, pale green, sap green.	Yellow or green.
Cupric oxide	Greenish blue, perceptibly green blue, azure blue.	Blue or green
Antimony oxide	Yellowish, yellow, brown-yellow.	Yellow
Uranic oxide	Sulphur-yellow, brownish, straw-color, greenish to green.	Yellow
Magnetic oxide	Medium brown, dark brown to blackish.	Brown or violet
Nickel	Earth color, medium brown, red-brown, sap brown greenish brown.	Brown

The Brickmaker.

TO PRESERVE WOODWORK.—Enquiries are being made in *Indian Engineering* as to whether coal tar or Burmese "earth oil" forms the best preservative for woodwork. Having tried both, observes *Invention*, we may state that when wood is exposed to air only, the earth oil is the cheapest and less offensive. For wood wholly or partially buried in the ground, or inserted in brickwork, the coal tar is much superior.

CANADIAN ARCHITECT AND BUILDER.

VOL. IV.—No. X. TORONTO AND MONTREAL, CANADA, OCTOBER, 1891. { PRICE 20 CENTS $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods,
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),
PUBLISHED ON THE THIRD SATURDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.
C. H. MORTIMER, Publisher,
14 King Street West, - TORONTO, CANADA.
64 TEMPLE BUILDING, MONTREAL.

SUBSCRIPTIONS.
The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.
Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.
Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

J. F. PEACHY	Quebec.

THE Ontario Association of Architects have had two competitions with the object of securing a suitable design for an Association seal. The results in both cases have been unsatisfactory. Here was the opportunity for some of the younger men in the profession to distinguish themselves. It is to be regretted that no one with the necessary ambition and ability could be found to take advantage of it.

THE American Institute of Architects will hold its twenty-fifth annual convention in the city of Boston on the 28th, 29th and 30th of the present month. It is announced that a number of valuable papers have been prepared for the occasion. There will also be an interesting exhibition of architectural drawings under the direction of the Boston Chapter. The occasion will in all probability be marked by a large attendance.

IT has been found for the present impossible to complete the tests of Canadian building stones recently undertaken at the School of Practical Science, Toronto, by the Ontario Association of Architects, owing to the incapacity of the testing machine. The authorities of the School have under construction a machine with double the capacity of the one at present in use. This machine, which will have a crushing capacity of 200 tons, is expected to be available within a month, when the series of tests will be completed, and the results in detail published.

ATTENTION is again directed to the CANADIAN ARCHITECT AND BUILDER'S competition for students of the Ontario and Province of Quebec Associations of Architects, which was announced in the September issue of this paper. It is earnestly hoped that a large number of students in the offices of members of both Associations will feel called upon to enter this competition and do their utmost to uphold the credit of their respective provinces. If this is done, the result will no doubt prove of much interest and value, and sufficiently encouraging to induce the holding of other competitions with a similar object.

A PERUSAL of the competitive advertisement columns of some of our contemporaries is occasionally refreshing (or depressing?). Here are two samples which are a little out of the ordinary type. Designs for a county jail in Wisconsin are wanted and the authorities "promise and agree to pay a *reasonable* price for plans and specifications which the committee may adopt." Possibly the ideas in regard to a reasonable price as entertained by the aforesaid committee will be very far from those of the poor deluded architects who may submit designs. A California school board offers a premium of $100 for plans and specifications of a $2,500 building. Truly, if a premium of 4 per cent. is offered for this amount of work the place must be an Eldorado for architects. But we hope no young Canadian will be tempted to go west on the strength of the offer.

THE City Improvement Board of Sydney, New South Wales, are of the opinion that "it should be compulsory for designs of buildings to be submitted to some competent body for approval, not only for æsthetic reasons and to secure some general harmony of character and design in contiguous edifices, but also to regulate the nature and class of buildings that should be permitted in particular localities." There is need for something to be done in this direction, not only in South Wales, but also in Canada. The practicability of carrying the proposal into effect may, however, be doubted. It would be difficult to secure

judges of design whose ability and fairness would not constantly be called in question, and equally difficult if such authorities did exist, to obtain their consent to occupy a position which would subject them to the ill-will of fellow citizens.

THE *Inland Architect* is of the opinion that "the enforcement of safe building can only be done by making owners, architects, and contractors criminally liable for accidents which result from a violation of the principles of sound construction broadly laid down in a general building act. A few prosecutions of this nature vigorously carried out would do more for safe building than any number of inspectors it would be possible to employ, and would besides create a most healthy public sentiment on the subject." More than this, it would prove a strong incentive to architects and builders to possess themselves of the knowledge required to enable them to know when they were building safely. It is to be feared that under present conditions, guesswork too frequently takes the place of exact knowledge, and so long as no responsibility attaches to the results of ignorance, there will always be those who will refuse to take the trouble to gain the information which would fit them to properly fulfil their duties. The Ontario and Quebec Architects' Acts provide for the proper education of architectural students in future, but in the case of the builder, no such standard of proficiency seems likely to be required.

WITHOUT reflecting upon the faithfulness to duty of the Inspector of Buildings for the city of Toronto, it should be declared that the inspection is a farce. Under present conditions it could be nothing else. During the present year the building restrictions which formerly applied only to the central districts, have been extended so as to cover the whole city. Notwithstanding that the area covered by the by-law has thus been doubled, the Building Inspector is still expected single-handed to see that its provisions are complied with. Not only so, but he is saddled with other duties as well. The proper inspection of buildings in a large and rapidly growing city like Toronto, is in itself beyond the ability of a single individual to properly perform. As a result, the building by-law is being violated in all directions. There is great need for the placing of this important branch of the civic service on a more satisfactory footing. Owing to the resignation of the City Engineer, the organization scheme which it was that gentleman's intention shortly to submit for the consideration of the Board of Works will not be likely to see the light. It is desirable, however, that a substitute for it should be formulated before the opening of the building season of 1892.

THE architects of Toronto should take a firm and united stand in favor of an improvement in the quality of the brick manufactured for use in that city. The brick at present supplied is to a large extent lacking in hardness and evenness of quality. For work of any importance the brick must be selected, and some one detailed by the architect to examine every load as it is delivered to see that the standard is being maintained. In instances where this precaution was not observed, it was discovered that there had been sandwiched in between every two or three loads of brick of the required quality, a load of the soft variety. This lack of uniformity in quality is due to the fact that the brick are burned in temporary kilns, through the uncemented joints of which much of the heat evaporates. In New York, where the brick is uniformly hard, manufacturers erect permanent kilns, such as are used in this country by the makers of pressed brick. This method should be adopted by large manufacturers in the vicinity of Canadian cities. Their claim that they cannot afford the expense involved in the erection of permanent kilns is not well founded. The extra price they would receive for first-class material added to the expense of erecting and pulling down temporary kilns two or three times each season, would in a short time recoup them for the required outlay. It is not likely, however, that any improvement will be effected until architects absolutely refuse to accept any but the best material.

THE Department of Architecture in connection with the School of Practical Science, Toronto, under the direction of Prof. C. H. Wright, is entering under favorable auspices upon the work of the second year of its existence. There are nine students in attendance as compared with five last year. Five of these are entering upon their course, three are in their second year, and Mr. C. E. Langley, of Toronto, having qualified himself by extra study, has passed into his third year. The results of the first year's work are regarded as being satisfactory, and the increased attendance gives encouragement for the future. The vacation work of the students bears evidence to the satisfactory character of the instruction imparted to them during their first year of study in this department. Mr. H. F. Ballantyne won the first year prize, presented by Mr. D. B. Dick for general proficiency in the first year in the Architectural Department. There are three good drawing rooms, capable of accommodating sixty students, and another is shortly to be added, together with private rooms for the professor, carpenter shop, model room, photographic studio and cement testing room. The lecture room will accommodate one hundred students. There is an excellent library containing many of the standard works on architecture, the sketches of the Boston Sketching Club, several useful volumes, remnants from the library of the Board of Architecture and Manufactures of Upper Canada, and the leading professional papers of Europe and America. The sum of $500 was spent on the purchase of architectural books last year. The intention this year is to exceed this sum by some $200. In addition to the library there is a department containing some 1,600 architectural photographs, ranging from ancient Egyptian to modern Gothic and ecclesiastical work. It is the intention by the aid of a stereoptican to enable the students to study these examples to the best advantage. The members of the architectural profession will watch the progress of the work in this department with the deepest interest and a desire to see its administration marked by the wisdom and liberality which will insure its continued prosperity, as well as the proper education of the succeeding generation of architects.

THE system of constructing public works by day labor instead of by contract, introduced in Toronto about two years ago, caught the popular fancy. The daily press strongly supported the new departure, and congratulated the citizens upon their escape from the power of unscrupulous contractors to rob them of their hard-earned contributions to the civic treasury. The opinion was expressed in these columns that the system would not prove as satisfactory as its advocates anticipated. Letters were obtained and published from the city engineers of leading American cities showing that in all of them the system of constructing public works under contract prevailed, and was regarded as being most satisfactory. An experience of two years has demonstrated the correctness of this position. One of the daily papers which most strongly supported the day labor method when first introduced, remarked the other day: "It is not clear that the city gets better work, and it is certain that the day labor method is more expensive than the contract system. The work is now being submitted to the test of a financial comparison with the results of the contract system, and reports indicate that for material and workmanship, sewers and roadways constructed by day labor do not compare too favorably with works done by contract under strict supervision." In support of this view a jury a few days since awarded damages to the amount of $1,800 to a workman who brought suit against the corporation for compensation for injuries sustained while in the city's employ owing to the attempt to do work too cheaply by omitting to provide necessary safeguards for the lives of workmen. While admitting that many contractors are not what they should be in the matter of honest dealing, it is unfair to include all, or even a majority of them, in this category, and a proper system of inspection should be sufficient in all cases to guarantee the fulfilment of the contract in accordance with the specifications. There can be no doubt that the experience gained by contractors who have been engaged for years on public works, coupled with the personal interests they have at stake, will enable them to perform such works at a minimum of cost which it is impossible for the city by the day labor method to achieve.

IT is to be regretted that a conflict of authority should have arisen between the City Council of Toronto and Mr. W. T. Jennings, City Engineer, resulting in the latter's resignation. It is admitted on all sides that Mr. Jennings has given the city good service. The point in dispute was whether the Council,

in the by-law under which Mr. Jennings assumed office, delegated to him the authority to control the salaries of the officials of his department. By-law No. 2534 fixing the duties and powers of the engineer provides that he shall have power to appoint such officers and clerks as he may from time to time consider necessary for the proper and efficient working of his department, and that he shall have power to suspend, dismiss and reinstate any officer, servant and employé of his department, and from time to time to prescribe their respective duties in lieu of or in addition to any duties prescribed by any statute or by-law. Sub-section 5 of the 26th clause gives him power "to appoint such foremen and inspectors and employ such labourers as in his opinion may be necessary to efficiently carry out any work under his control; and all such inspectors and foremen shall be paid such wages as shall be determined upon by him, subject to the approval of the Committee on Works." This clause is the only one in the by-law which gives the engineer authority to determine the salaries of his assistants, and this authority applies only to inspectors and foremen, and is to be exercised subject to the approval of the Committee on Works. Mr. Jennings seems therefore to have proceeded on a false assumption in claiming that the right to control salaries was conferred upon him at his appointment. On the other hand, the fact that the by-law does not confer upon him this authority, rendered unnecessary the passing by the Council of the amending by-law. It is unfortunate that Mr. Jennings should have written the letter he did to the Council, as it served to accentuate the difficulty. Had a friendly conference taken the place of that letter, no doubt the matter could have been satisfactorily adjusted. As it was, arrangements were proceeding satisfactorily for an amicable settlement when the Board of Trade held an indignation meeting on Mr. Jennings' behalf, which could have had no other effect than to confirm the attitude of those who had placed themselves in opposition to the stand which that gentleman had taken. One of the aldermen, who was also a member of the Board of Trade, was refused a courteous hearing when he essayed to make an explanation at that meeting of his course of action in the Council. In the light of these circumstances it cannot be surprising that the Council should have resented the action of the Board of Trade by voting down all proposals for a reconsideration of the matter. There was force in the remark of one of the aldermen, that while the members of the Board of Trade decline to serve the city in the capacity of aldermen, they have shown their willingness to dictate what the conduct should be of those whom the citizens elected to represent them. If the Board is not prepared to do more than find fault, it will best serve the public interest by confining its attention solely to commercial affairs. The important duty now devolves upon the Council of appointing a successor to Mr. Jennings. Matters of great moment require attention, and forbid that the appointment should be delayed longer than is absolutely necessary. On the other hand, the very importance of the matters to be entrusted to his hands demands that the person to be appointed should be possessed of the character, education and experience which are necessary to enable him to exercise wise administration. Prior to entering upon office, a clear and definite understanding should be arrived at touching his duties, authority and relations to the Council, such as will prevent the recurrence of misunderstandings like the present one.

TORONTO ARCHITECTURAL SKETCH CLUB.

ON Monday evening, October 5th, was held the annual meeting of this club in its new rooms, cor. Yonge and Gerrard streets. There was a fairly large attendance and much enthusiasm.

After the minutes of the last annual meeting had been read and confirmed, the treasurer, Mr. A. C. Barrett, presented his report, showing that the columns of the cash book were like two forces in equilibrium—pretty evenly balanced. This is very satisfactory, considering the many expenses the Club has had during the year.

The retiring President, Mr. S. G. Curry, made a few remarks, giving a short description of the work accomplished, and urging the necessity of the members putting forth a renewed energy. He drew attention to the fact that if members expected architects and others to continue preparing for them papers, they must make a point of keeping up the attendance, as it could not be expected that busy men would give up valuable time if it were not appreciated.

After several proposed changes in the constitution had been adopted, the nomination and election of officers was proceeded with, the following being elected:—President, Mr. J. A. Pearson; Vice-President, A. C. Barrett; Secretary, C. H. Acton-Bond; Assistant Secretary, Murray A. White; Treasurer, T. R. Johnson; Directors, C. J. Gibson and E. B. Jarvis.

The Club has now very comfortable quarters, which, with a little judicious decorating, will be a credit to so artistic a body. Visitors will at all times be welcome, a hearty invitation being extended to all who are interested in the aims and objects of the Club.

OUR ILLUSTRATIONS.

PHOTOGRAVURE PLATE—ST. PAUL'S CHURCH, BLOOR STREET EAST, TORONTO.—MESSRS. EDWARD AND GEO. K. RADFORD, ARCHITECTS.

This church was erected about the year 1856. The Building Committee, which was composed of Messrs. W. A. Baldwin, J. O. Brown, Rev. Saltern Gibbons and Thos. Henry Ince, invited competitive designs from the local architects. In response to the invitation, four or five designs were submitted. The one now published, by Messrs. Edward and Geo. K. Radford, was accepted, and the building erected in accordance therewith. The Messrs. Radford, who came from England, resided but a short time in Toronto, and carried out no other work of importance in this country.

BROCK MEMORIAL CHURCH OF ST. SAVIOUR, QUEENSTON, ONT.—S. H. TOWNSEND, ARCHITECT, TORONTO.

ALTERATIONS TO WAREHOUSE ON ADELAIDE STREET WEST, TORONTO.—DENISON & KING, ARCHITECTS, TORONTO.

DETAILS OF CHOIR STALLS, SOUTH SIDE ST. PAUL'S CATHEDRAL, LONDON.

These details were drawn by Charles Wm. Baker, and were awarded the silver medal of the Royal Academy.

CHURCH ARCHITECTURE.

MR. JOHN WILLS, F. S. Sc., architect, of Derby, Eng., who is a delegate to the Methodist Ecumenical Conference at Washington, D. C., addressed a meeting of Methodist ministers in Toronto recently on the subject of "Methodist Church Architecture." He also exhibited a number of his own drawings from which churches have been erected in different parts of England. Mr. Wills recommends that there should be at least four means of egress for all large churches. He thinks the Gothic, properly and carefully adapted to modern forms of worship, the most appropriate style of church architecture. He is of the opinion that the situation of the organ and choir should be either behind the minister or in the same end in one of the transepts. Concerning methods of heating, his preference is for the hot water low pressure system.

PUBLICATIONS.

The Adamant Manufacturing Co., Toronto, have issued a neatly printed pamphlet explaining the nature and advantages of their new plastering material.

We are indebted to Mr. William Mueller, bookseller and importer of works of Art, 695 Broadway, New York, for a copy of "Academy Architecture and Annual Architectural Review," for 1891, edited by Alex. Koch, architect, and containing a selection of the most prominent architectural drawings hung at the Royal Academy Exhibition, and a review of interesting architectural subjects carried out or designed during the last few years in England and abroad.

In the November number, the *Cosmopolitan* will publish a series of letters written by Gen. W. T. Sherman to one of his young daughters, between the years 1859 and 1865 and covering most of the events of the war of secession. These letters present graphic pictures of a great soldier amid some of the stirring scenes in which he was a giant figure, and in them the patriotic spirit of the Federal general is seen to have been most attractively tempered by a strong affection for the Southern people.

PERSONAL.

On behalf of a Canadian syndicate invited by the government of Russia to tender for the construction of the eastern part of the Siberian railway, Mr. Geo. A. Keefer, the well known civil engineer of Ottawa, lately set out for the land of Russian exile. Mr. Keefer's experience in connection with the construction of the C.P.R. through the Rocky Mountains, well qualifies him to serve the interests of his present employers.

PROF. BOVEY.

PROF. Henry Taylor Bovey was educated at a private school in England, and at Cambridge University. On entering the University he competed for and obtained an open scholarship. On graduation he took a high place in the mathematical tripos, and shortly after was made a fellow of Queen's College. Having decided to adopt the profession of engineering, he joined the staff of the Mersey Docks and Harbour Works. He was shortly appointed one of the assistant engineeers on this work, and in this capacity had charge of some of the important works then in progress.

In 1877 he was appointed Professor of Civil Engineering and Applied Mechanics in McGill University, Montreal. The engineering courses in the University were at that time managed as a department of the Faculty of Arts, and were without buildings or equipment. In 1878, however, a department of Applied Science was constituted, and Prof. Bovey was elected its Dean. The magnificent endowment of the late Mr. Thomas Workman and Mr. W. C. McDonald have afforded Dean Bovey an opportunity for the display of his great executive ability and untiring energy.

Much of the success of the Canadian Society of Civil Engineers is without doubt due to Prof. Bovey's labours as its Secretary, which position he occupied continuously from the foundation of the Society until within the past few months, when increasing college duties compelled him to resign the office. Prof. Bovey is a Fellow of the Royal Society of Canada, a member of the Institution of Civil Engineers, as well as of several other engineering societies.

PROF. BOVEY.

PASSING EVENTS.

"IT is a singular fact," said a well-known Toronto plumber to me the other day, "that not one builder in twenty appears to know what the proper dimensions are for stationary wash tubs. It is still more singular that they are continually applying to me for the information. One would suppose a carpenter would know more about the matter than a plumber. In order to be in a position to answer my numerous enquirers on this subject, however, I have jotted the information down in my note book, and here it is: 'Inside measurements—15 inches across bottom, 23 inches across top, 15½ in. deep and 25 in. in length for each compartment.'" Thinking that possibly the information might be of service to many readers of the ARCHITECT AND BUILDER, I give it for publication, trusting also that by doing so I shall assist my friend, the plumber, to save a portion of his valuable time.

* * *

Builders and others intent upon disregarding the law which compels a permit to be obtained previous to the erection of any new buildings, occasionally get an opportunity to laugh at the expense of the Building Inspector. Such an individual made application at the Inspector's office the other day for a permit to erect a dwelling, and having obtained it, turned round and cooly informed the official that he had just completed the house and moved his family into it.

* * *

I wonder how many of our city architects are thoroughly familiar with the provisions of the local building ordinance? A member of a leading architectural firm learned for the first time the other day, of the existence of a provision in the local by-law prohibiting the use of certain materials in partition walls, notwithstanding that the by-law has been in operation for two years. Architects will save themselves and their clients time and expense by acquainting themselves with the details of the regulations governing the construction of buildings.

* * *

Apropos of your editorial remarks on the growth of incandescent electric lighting in Toronto, a prominent official of the C.P.R. Telegraph Company directed my attention a few days ago to a new business building in course of erection on a leading thoroughfare. "Do you know," said he, "that there isn't a gas pipe to be found in that building? It is, as you see, wired throughout for electric lights. The intention is to depend entirely upon the incandescent light. I regard this as a striking illustration of the rapid strides which the electric light is making. Two years ago, no architect or owner of a building would for a moment have considered the question of dispensing with gas."

* * *

A Montreal architect remarked to me the other day that architectural students in Quebec are at a disadvantage as compared with students in Ontario. Being asked in what particular, he pointed to the use of the dual languages as being one serious drawback and also to the fact that well-equipped free public libraries, such as the one in Toronto, are not at the disposal of the students of Quebec. There is no doubt some foundation for this view of the case, and consequently the greater reason to hope that the Quebec Association of Architects will exert itself to the utmost during the approaching winter to provide such instruction for the students as shall, to a large extent at least, make up to them the loss sustained in the direction referred to. The students should scarcely need to be reminded that upon the extent of their own efforts will most depend their advancement.

PASSERBY.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

A MEETING of the Council of the Ontario Association of Architects and students of architecture was held in the rooms of the Association on the 5th inst. Mr. F. X. Berlinguet presided. The principal business before the meeting was to make arrangements for the instruction of the students during the coming winter. Messrs. Taylor, Raza, Hutchison and Dunlop were appointed a Committee to arrange a programme, which should include a series of lectures, and if possible, classes in architecture. The success of the undertaking will depend largely upon the students themselves. If they show their appreciation of the efforts which the Association is making for their benefit, by being present at the lectures and classes whenever it is possible for them to do so, satisfactory results are certain to follow.

A strong feeling seems to exist here in favor of a Dominion Association of Architects, and it is not improbable that at the next meeting of the Ontario Association a deputation from this province will be on hand to confer with the members concerning this most important subject.

Mr. Hadrill, the Secretary, reports that upwards of $175,000 has been subscribed for the erection of the new Board of Trade building. It is expected that the full amount required will be secured shortly, and that construction will begin early in the spring.

The practice of proceeding with the erection of buildings without complying with the by-law which provides that a permit must first be obtained from the office of the Inspector of Buildings, prevails largely in this city, as in the cities of Toronto, Hamilton and elsewhere. During the past week this practice of violating the law led directly to the death of a workman named Theodore Pouliot, employed on a building in course of erection by a contractor named Elzear Chenet, at 116 Desrivieres street. Chenet drew the plans for the building himself, and went on with construction without a permit. One side was constructed of planks three inches thick, laid horizontally one above the other and tongued and grooved, supported only by a post at each end. Under the weight of the last storey this wall bulged out at the center near the foundations, and the structure collapsed, killing Pouliot as stated. Mr. Lacroix, the Inspector, testified at the inquest that owing to a defect in the by-law persons intending to build were not required to submit plans of the proposed building, but only a general description, and that while Chenet should have notified him three days before the foundations were commenced, he did not do so until two days after the roof was on. It was shown that the contractor had obtained a blank form which he should have filled in and returned to the Inspector's office before proceeding with the work, but which he did not so return. Because this form was not handed in, the Inspector concluded that work had not been commenced. The jury brought in the following verdict: "We find that the collapse of the house No 116 Desrivieres street on Friday evening was due to bad workmanship and the want of experience on the part of the contractor, Elzear Chenet; moreover, we censure the Building Inspector for having given permits without knowing it the building had been started or not." Is it not time that a severe example was made of those who wilfully disregard the city building ordinance? It is also clearly desirable that all persons proposing to build should be compelled to submit plans for the approval of the Inspector of Buildings.

The Roads Department has expended thus far $355,371, out of a total appropriation of $406,642, leaving a balance in hand of $51,271. In addition there have been large expenditures for permanent pavements, the funds for which have been secured by special loan.

"CANADIAN ARCHITECT AND BUILDER" STUDENTS' COMPETITION.

WITH the object of promoting a feeling of friendly emulation on the part of students in the offices of members of the Province of Quebec and Ontario Associations of Architects which should result in improving the skill of the young men thus engaged, the publisher of the CANADIAN ARCHITECT AND BUILDER invites competitive designs for a suburban cottage to be occupied by a young man doing business daily in the city, owning the lot, possessing $2,000 in cash and having an income of $1,500 per annum.

The cottage is to be erected on an inside town lot having a frontage of 75 feet, a depth of 150 feet, and situated on the west side of the street.

There is required in the way of accommodation a parlor, small library, dining room and kitchen; cellar, suitable for heating apparatus and storage of fruit and vegetables.

On the first floor there are to be four bedrooms and bathroom.

The attic is to contain a servant's bedroom and store room.

The materials to be used shall be brick on a stone foundation.

There is no sewerage or water supply systems in the town, and the owner will have to dispose of all waste in the most sanitary manner, avoiding contamination of the soil from which he has to draw his supply of water.

Competitors are required to submit plans of the various floors, two elevations, unless accompanied by a perspective, when one will do.

Drawings must be made on sheets of heavy white paper or bristol board, 14 x 20 inches in size, and must be drawn sufficiently coarse to allow of their being reduced to one-half the above size. Drawings must be made in *firm, strong lines*, with *pen* and *black* ink. No color or brush work will be allowed. Each drawing must be marked with the *nom de plume* of its author, and the author's name, *nom de plume* and full address must accompany each drawing sent in. Competitors must also give the names of the architects in whose offices they are employed.

Drawings must reach the office of the CANADIAN ARCHITECT AND BUILDER, 14 King St. west, Toronto, not later than the 5th day of November next.

The right is reserved of publishing any design sent in. All drawings will be returned to the authors within a reasonable time after the competition is decided.

The first premium will be $15; second, $5; third, one year's subscription to the CANADIAN ARCHITECT AND BUILDER. A premium of $5 will be given for the best perspective sent in. The decision as to the respective merits of the designs submitted will be made by Mr. Thos. Fuller, chief architect, Department of Public Works, Ottawa, which decision will be final.

This competition is confined to students practising in the offices of members of the Province of Quebec and Ontario Associations of Architects.

TO CORRESPONDENTS.

IF the correspondent who sends us an enquiry signed "Subscriber" will comply with a well known journalistic rule by forwarding his name and address (not for publication), his question will receive attention.

A great deal of ingenuity is being expended upon machines and devices for sawing stone directly out of the quarry, and while thus far no positive success has been achieved, several machines are so near it as to suggest that the time is not far off when the result will be reached. Success would revolutionize and greatly reduce the expense of quarry working, and this in a time when there is so much competition in building materials, many of which are displacing stone, owing to superior cheapness in first cost, would be a boon to the quarry interests. The channeller, however, as yet stands as the only practical every-day quarry machine, but invention is after it with an energy that bids fair to be successful in no great time.

SPECIAL NOTICE TO CONTRACTORS.

THE special attention of builders and contractors is directed to a series of articles to be published in the "CANADIAN ARCHITECT AND BUILDER," and which are being prepared by a properly qualified quantity surveyor, with the object of instructing master builders and contractors in the methods of taking off quantities and arriving at a true estimate of the cost of erecting various kinds of buildings.

Designs and specifications of a dwelling, church, store, public building, etc., will be published, and practical illustrations given of the method of arriving at the quantities of materials pertaining to each of the several trades.

The value of this information to every contractor will be at once apparent. It will serve to replace the hap-hazard methods of estimating at present largely practiced, and which are responsible for many of the failures in the building trades, by a system which can be relied upon as being accurate.

This series of articles will be commenced in the CANADIAN ARCHITECT AND BUILDER for November, and will probably extend over a period of from one to two years.

For the usual subscription price, $2, the CANADIAN ARCHITECT AND BUILDER will be sent to new subscribers from November of the present year to the close of 1892.

Every contractor who desires to profit by the information given in this series of articles should at once become a subscriber.

THE BUILDING TRADES IN MODERN PRACTICE.

By GEORGE H. BLAGROVE.

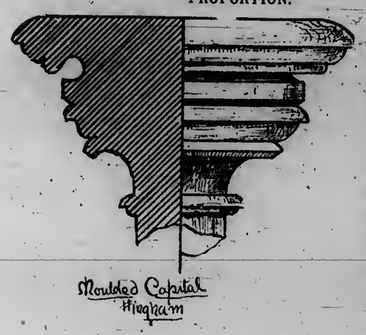
THE different densities of building materials have been studied with reference to the weight of their materials, their resistance to crushing, and their power of absorbing water. We frequently employ a harder and denser species of bricks in foundations than elsewhere, but beyond this there are few attempts made to dispose the materials of a building according to their density, for structural reasons. If materials of different densities are found in various parts of a building, it is usually with regard to their external appearance that they are so arranged. Yet it would not be difficult to design a large building in such a manner that the weight of its materials should be diminished towards the top, not so much by reducing the thickness of its walls as by the employment of lighter materials in their construction, thus combining the advantages of diminished weight with those of statical stability. In damp situations, the denser materials are generally preferred on account of their non-absorbent character, but the reason for this preference disappears when the outer surface is vitrified or otherwise rendered impervious.

Hollow walls, for the exclusion of damp, allow us to vary our materials on the interior and exterior, while the air-space serves for protection against changes of temperature. If we build one section of our hollow wall of substantial thickness, the other being only a half-brick or thin stone casing, and the two being connected by means of galvanized iron bonding cramps, the question arises whether the greater or lesser thickness should be placed outside.

It has been maintained by some that the greater thickness should certainly be placed on the outside, because it allows less damp to find its way into the cavity, such damp being quickly evaporated by the warmth of the dwelling. On the other hand, it has been pointed out that under such an arrangement the greater section of the wall must be permanently charged with damp, with disastrous results to any woodwork connected with it, and that if the cavity is to be dried by the warmth of the dwelling this can only have the effect of drawing the damp inwards, to the detriment of health and the destruction of wall paper. It is contended that these evils are avoided by placing the smaller section outwards, where, if it is the sooner penetrated by damp, it is the sooner dried in warm weather. Some are in favor of ventilating the cavity, for the purpose of keeping it dry, while others contend that this at once destroys the advantage of protection against rapid changes of temperature. It has often been found, however, that the cavity in a hollow wall, when it has no outlet, contains an accumulation of moisture, which gradually soaks through the inner section to the interior of the building. The cavity, if not ventilated at top and bottom, should have outlets for moisture at the bottom; and some persons go so far as to require that a cement splay be formed at the bottom of the cavity to throw the accumulated moisture outwards. It is certainly a good plan, where doors and windows occur, to introduce sheet lead at the head of the opening, the lead being turned up on the inside and down on the outside, so as to afford protection to plates and lintels.

As to the difference in cost between solid and hollow walls in brickwork, it has been calculated that where the inner and outer sections and the intermediate cavity are each of the same width, there is a saving of one-third in the number of bricks and one-half in mortar. The cost of cramps, or any other special means of bonding, must be added, and as the resistance to thrusts, the resistance being augmented by 20 per cent. in weight over brickwork. We have a substance which precludes damp more effectually than most kinds of stone, and which enables us to cope most satisfactorily with the modern increasing demand for rapid execution in building. We cannot urge much in favor of the external appearance of concrete walls, but with brick and terra cotta quoins, copings, window dressings and other accessories, there should be ample opportunity for the production of artistic effects. One of the objections raised against concrete buildings has been that they are difficult to pull down. This objection may commend it to the attention of those who will regard it rather as an advantage than otherwise. —*Specialties.*

PROPORTION.



THE whole secret of design in architecture may be summed up in the terms Proportion and Expression, for the differences which mark off one style from another are those mainly derived from the form and proportion of the openings, says *The Building News*. Professor Banister Fletcher, in his opening address to students of architecture at King's College, very appropriately alluded to the subject of proportion, which he illustrated by taking the openings of somerset House, and by showing by model the effect of first a doorway of half its width in height, next making it a square opening, then adding one-third of the width to the height, and lastly, making the height twice the width.

Though the low opening may be really high enough for a doorway, the mind naturally reverting to the human figure as a standard of proportion, or, to the "fitness" of things, at once condemns the proportion as bad for a doorway. We sometimes, it is true, see wide entrances to the pits of theatres, drill halls and warehouses; but they invariably look out of proportion—that is, they appear awkward and offensive to our sense of fitness. Even in some Queen Anne houses we have seen doors of about a square; which looks contrary to our standard, because we naturally recall to the mind the human proportions, though, as a matter of actual use, the wide opening may be an advantage in getting in or out large pieces of furniture. The manner of teaching proportion which the professor adopted, has the merit of ocularly demonstrating one of the essential principles of design, for there are many people who imagine that a few inches more or less in the width of a door or window make no difference whatever. The same disregard, or ignorance, of a pleasing proportion is seen in the planning or selection of rooms, as if it made no difference whether the room was square or oblong, and that furniture of a certain size and shape could be made to look equally as well in a square room as in an oblong room. The window, like the door, has its own pleasing proportion. We can widen a window, as Prof. Bannister Fletcher says, but we can easily spoil it by the operation unless we take care to preserve the unit of proportion by sub-dividing the width by mullions, as in a gothic window, or by bringing the eye to rest on proportion of one of the panes. But it is absolutely essential to preserve some unit or individual part in a wide window, or it would be quite as offensive as a wide doorway.

The lesson of proportion need not stop at windows and doorways, it can be applied not merely to plans of apartments and their heights, but to the art of composition itself. For example, Prof. Fletcher might have shown that into his first illustration of breaking up a plain building front into parts proportion enters. If, for example, we take a long, straight facade, perfectly flat of blank wall, or with windows in it, equally distributed, we may have a proportion that offends by its length and monotony. But break it up by projecting or recessing certain parts, say the two extreme ends and a wide centre, and the proportion of the whole is greatly improved, for although not an inch of height has been added the eye is arrested by the three individual parts into which the whole facade has been divided, and the extreme length, being broken by oblongs of the contrary direction, is rendered less fatiguing to the eye. By further dividing, or by making vertical lines, the proportions may be still more altered. The effect mainly due to the fact that the eye attends to the smaller individual parts instead of the whole. To take a concrete case, a continuous barrack front looks much longer than an equal length of houses forming a street of the same height, because each separate house being an upright oblong, arrests the eye, and the number of stories forms a scale to its real height. In design, then, the value of proportion is in composing the individual parts or subdivisions by giving them the proper ratio of height to width, and so drawing the eye from the proportion of the whole mass to that of the individual parts. What better illustration of this can be found than in towers? We constantly hear people talk of the proportion; it is either said to be squat or too tall, referring unconsciously to a standard in their mind's eye, from which they cannot get away. Thus, for example, St. Paul's dome would look very squat after looking at a tower and spire like that of Salisbury, and many towers would look too short after seeing the Boston Example. The proper proportion of any particular tower can only be judged by the individual parts or stories of which it is composed. It may look exceedingly tall and disproportioned if the belfry windows are small, and a mere repitition in every stage, but by subdividing the height into stories of unequal height, and by making the openings small here, and large there, the proportions will be pronounced excellent. Therefore, proportion is not a matter of mass only, though, of course, we have to see our buildings through dense fogs sometimes, when they ought to look pleasing, but is chiefly to be studied in the smaller parts of design. Bad proportion in a window, a door or a fire-place, will always be an eye-sore in a room, however well proportioned it may be, the same want of pleasing ratio will spoil a wall paper, the panelling of a door or dado, or any ornament, though the eye in the latter cases would have to be more educated. The ordinary sense of fitness in proportion is, however, pretty general; and, roughly speaking, we may say, that it exists amongst people almost as strong as the sense of harmony or music. As a discordant note jars on the faculty of hearing so we find a glaring disproportion, or want of fitness, produces an unpleasant sensation on the mind.

Proportion is, however, not confined to ratios and dimensions; we experience its influence in the right proportion of mass to detail, of plainness to ornament, and these are quite as necessary to learn by those who are studying artistic kinds of expression. The value of models or illustrations in the designs of carpets, wall papers, decoration applied to furniture and metal work is apparent. We often see patterns offensively obtrusive and distractive, owing to the want of quiet surfaces or a due intermixture of ground and pattern; furniture full of unrestful twists and turns and carvings that distract rather than please; because the artist has not realized a sense of proportion between the plain parts and the ornament. These are things that can be taught by showing how much ornament can be placed on one part without overloading it, what surfaces or members should be plain, and which may be enriched. The whole question of ornament is one of "more or less." The amount of ornament on a surface must indeed be in inverse ratio to the height of relief. Thus every square quarter inch on a Benares brass bowl may be occupied with incised ornament without offence to the eye, for the lines are narrow and the relief exceedingly low; but in repousse work of massive relief in the same metal, anything beyond a simple device broadly treated is felt instinctively to be intolerably coarse. To teach applied design on rational principles, the student is in need not merely of examples in the art he is studying, but of demonstrations or models that will show him the most agreeable combinations. He should not be taught to copy furniture and decoration of various masters and styles; but be taught to realize for himself the due proportion between structures and forms of the plainest and most direct kind and the ornament that should accompany them. It is in these more extended ways we may learn the values of proportion in the arts of design, and not merely in regard to the heights and widths and openings, the proportions of columns and entablatures, and of apartments, which appear to be the only kinds of proportions that are recognized by the Classic revivalists.

MAKING BLUE PRINTS.

According to the *Brickmaker*, the following formula can be used for preparing a quantity of blue print paper at once, and which can be laid aside to be used as wanted: Mix in one bottle a solution of two and one-quarter ounces of water to each ounce of citrate of iron and ammonia, and in another one ounce of red prussiate of potash to each eight ounces of water; these solutions if well corked will keep indefinitely. To use, mix one part of the iron solution with two parts of the potash just before using, and with a soft sponge flow over the surface of the paper a heavy coat and remove the superfluous liquid, stroking in one direction, dry the paper quickly and hang it in the dark. When dry it will keep well in a dark box, and will make clear, bright prints.

SANITATION AND HEALTH.

PUBLIC WATER SUPPLIES IN THE PROVINCE OF ONTARIO.*

BY WILLIS CHIPMAN, C. E.

IT is now an acknowledged fact that in cities and towns without a public water supply and without a sewerage system, the death rate is higher than in the rural districts or in those cities and towns that have availed themselves of these evidences of civilization.

From the standpoint of the economist no town of a population of 1,000 people can afford to be without a public water supply for fire protection, as the interest on the first cost will be met by the decrease in insurance premiums, while from the standpoint of the philanthropist, the humanitarian and the medical health officer, no town should be without an ample supply of pure water for domestic purposes, and a system of sewers to carry away the water used and the wastes with which it will be burdened, to such point that no danger can arise from its disposal.

In Canada we find that the first public water supply of any importance was introduced into the City of Montreal by a private company in 1801. These works were sold to another company in 1816, to a third company in 1832, and eventually to the city in 1845. New works were constructed by the city in 1853-56.

The next city to introduce a water supply was St. John's, N. B., where in 1836 a company constructed works which were abandoned in 1849-50, when new works were built. In 1855 the city purchased the works.

In Toronto, water works were constructed in 1841 by a company which operated them until 1873, when the city purchased the works.

Halifax purchased her water works in 1861 from a company which constructed them in 1845-48.

These were the only works in Canada in 1850. In 1860 we had nine works, in 1870 ten; in 1880 twenty-nine, in 1891 the number of cities and towns supplied with water works is nearly one hundred, but in about twenty of these the supply is for fire purposes only.

We will now consider the water works of Ontario only.

In this Province about 30 per cent. of the water works are owned and operated by private companies, while the population served is probably not 15 per cent. of the total supplied. The average total family rate in Ontario is about $20 per annum in works owned by municipal corporations and $25 per annum where owned by a company. The cost of works in Ontario is about 35 per cent. less per family in private works and the charge 20 per cent. more than where works are owned by the municipal corporation.

There are 44 cities, towns and villages in which the water works are now owned and operated by the municipal corporation, 13 of these being for fire protection only. Private companies own and operate 14 water works, in one of which (Napanee) the water is of such exceedingly bad quality that we will classify it as for fire purposes only.

In the majority of these 14 towns and villages the expenditure of a comparatively small additional amount would have secured an ample supply of pure water for domestic purposes as well as a fire supply, would have decreased the death rate and disease, and would probably bring in a revenue after paying operating expenses.

In many of these towns engineering advice was not sought, and in a few it was not followed.

In some of these towns the water is used for lawn sprinkling, for cattle and horses, for baths, for water closets, for all purposes except drinking and cooking, and the temptation may often induce people to use it for these purposes as well. Herein is a great danger. Water once drawn from a tap and used for drinking and cooking will probably continue to be so used until sickness occurs. To those towns supplied with elevated tanks, reservoirs or stand pipes in which to store the fire service water, the foregoing remarks especially apply.

These results are convincing that the private companies in the Province of Ontario now supplying water to cities and towns on the franchise plan are not giving these towns as good water as other cities, towns and villages are supplied with. In only one place is subterranean water being supplied, and in this place it was forced upon the company.

"Quantity" rather than "quality" is their motto.

The short-sighted municipal finance minister who, only considering water works from the standpoint of dollars and cents, revenue, interest and running expenses, and the silver-tongued (fingered?) franchise agent, are often (separately or jointly) directly responsible for the selection of so many inferior water supplies throughout the Province.

Where water works are contemplated, the local boards of health should investigate intelligently and thoroughly before adopting for a public supply a water that is of a suspicious quality or one liable to future pollution.

Analysis of water as now generally conducted are a humbug and a delusion, the honest scientist being no match for the wily manipulator. The color, taste, smell and temperature of the water supplied, and a study of the conditions surrounding the drainage area from which the water is drawn are of greater weight than any analysis in determining the purity of water. The problem of possible pollution from sewage or from farm drainage in the future should also be carefully considered.

In all cases the problem of selecting a source of supply should be carefully considered and reported on by some disinterested authority before the works are designed, and the schemes and machinations of the disciples of "quantity rather than quality" should be met by the remonstrances of all sanitarians.

* Abstract of a paper read before the Association of Medical Health Officers of Ontario.

PLUMBING PRACTICE.

IT is not expected that every plumber is possessed of knowledge requisite to thoroughly distribute water in all parts of a building, with equal facility to each floor upon which is placed plumbing apparatus, says *Fire and Water*. Where high pressures exist little difficulty is experienced, provided frictional resistances and cross section of area of pipe and branch supplies are considered in their relations to each other. It is often said by way of excuse for bad judgment in the plan of local distribution that there is a lack of pressure, when it is found to be a lack of volume of water—(pipe not large enough). It is a common practice in local distribution for plumbers to run one size of pipe throughout the entire building, with branch connections of same size on each floor, apparently forgetting or ignoring the fact that each added length, whether vertical or horizontal, increases friction, diminishes pressure and reduces flow.

In order to overcome these difficulties, a little study upon the subject will be a great help to the progressive plumber. A study also upon the question of "taking out branch supplies" from "the main supply," as to the angle of connection, will be found to be profitable. A great deal of pains is taken with water-pipe connections; as to angle of connections, the same rule applies with more force with respect to branch supply from main supply. Right-angle connections are very pretty as lines of harmony, but in water-pipe practice they should never be allowed. The rule of following parabolic paths or curvatures in connections will largely lessen friction and preserve the continuity of a water column passing from one line of delivery to another.

HOUSE HEATING IN THE FUTURE.

OBERLIN SMITH in a lecture before the Franklin Institute, at Philadelphia, spoke as follows of the possibilities of the displacement of coal in favor of gas or electricity for heating purposes:

"In the matter of warmth there is certainly an inviting field for our future inventors. That our present methods of heating by the burning of coal and the non-burning of smoke, and of cooling by carrying in lumps of ice, are crude and wasteful, as well as extremely irregular and uncomfortable, it is not necessary to argue about. It seems probable that in the near future, at any rate for our cities, some system of gas heating will displace coal and wood to a large extent, and this is the more likely from the fact that our streets and houses are already supplied with the necessary pipes, which may perhaps be gradually thrown out of use, as conveyors of illuminating gas, by the improvement and development of electric lighting. There also seems a tendency among inventors in recent years to attempt some kind of artificial cooling by the distribution through pipes of cold air or freezing mixtures of varying kinds; also to contrive cheap ice-making or other cooling machines, which can be economically used in individual buildings. All this is in a direct line of progress, but it seems probable that at some time in the future we shall depend upon the electric current brought into each building through a single wire, not only for our lighting and power, but for our heating and cooling also. Just how the latter process is to be accomplished we do not yet know, but reasoning by analogy, it would not seem outside the range of possibility when we consider the fact that the burning of coal in a furnace can be made to produce heat or cold at will. It is true that while electric heating in itself has been proved to be perfectly practicable, yet at present it is not economical. This is owing to the fact that our best and largest steam engines by which we run our dynamos utilize only from 10 to 15 per cent. of the energy stored in the coal, lavishly wasting the remainder. Fortunately, our dynamos have reached an efficiency of about 90 per cent., so that there is not much waste in using the electric current after the power to produce it is once generated. It is probable, therefore, that the use of electric heating will for the present be somewhat limited, and confined to special places where its convenience will offset its extra cost. For an extension of its employment thus, as for certain other important uses of electricity, and upon a scale far beyond anything we can now imagine, we must wait until we learn how to produce this current of pure energy from the coal or other fuel direct. Than the accomplishment of this feat, there is to-day no more fascinating problem in the realms of science. Many are working at it, with as yet but small success. We need not despair, however, as it seems to be a logical possibility, and the only thing required is to find out how to do it."

DECORATION AND FURNITURE

GLASS PAINTING.*

THE art of stained glass is not yet fully fortunate in speaking a language understanded of the people. Indeed, "I don't understand stained glass," is the remark one most frequently hears made about it, and this even from people of considerable appreciation for other forms of art. This comes home to one when one sees what pitiful stuff people of taste are content to have in the doors and windows of their own houses. The purplish birds on the yellow leaves within a circle of harsh red, the whole backed up by alternate oblongs of bad pink and green; how frequently one notices that work of art standing where it ought not! The builder inserts this and the like of it in the first instance, but the occupants suffer them to remain, not perhaps confident that they could find anything else so much more agreeable to their feelings as to warrant the expense of a change. It means, perhaps, that about even the highest development of the art, as usually practised, there still clings conventionalities of the parasitic or stifling sort; traditions that have arisen, that could only arise, in a period of bad art, and that have survived into a time of better things.

Wholesome conventionality, the acknowledgment of limits, and the determination to pull up well within them, is of the nature of a backbone to decorative art. Excellent, too, is healthy tradition. A man, or a school of men who have practiced a craft right well, bequeath to their successors, not a series of cast-iron rules and regulations, but a common-sense recommendation: "On such and such lines our art can be successfully carried out; adhere to them, we advise you, and see your way very clearly before you try to disturb them. If new possibilities arise, they must be dealt with! but do not change the old order for less than sufficient cause." Without some such tradition, a craft may become experimental and amateurish, and its productions perplexing.

Let us, before going further, try and understand stained glass.

The germ of it lies, not in the wooden-framed sash-windows with which we are most familiar, but in lead lattice, or, as it is perhaps most often called, casement. The simplest form of lattice consists of square or diamond shaped panes of white glass of the same size, connected by "leads"—that is, by strips of that metal, with a groove on each side, into which the glass fits, the leads being joined by soldering at the corners, and the interstices filled in with cement corresponding to the putty in our sash windows. From this simplest form of a lead-latticed window, the next step is the introduction of coloured glass. By this we get square or diamond-shaped panes alternately of white and colour, or of several tints in succession—a series of arrangements being possible whilst we still cut our glass in panes of straight-lined shapes all of one size. More variety comes with the half-step from this to panes still rectilinear, but of different sizes and shapes; and we have made a stride when we have found out how to cut our glass into pieces with curved outlines. Our framing line of ductile lead is as ready to go round a circle as along a straight line, and now with curve-contoured forms of varied colour arranged in groups, we have already a handsome stained glass window of pattern.

The next move is a momentous one, and may have a word of preface. The best ornamentist of the present time* has acutely noticed that some simple pattern shapes, that have been assumed to imitate natural forms, are in reality dictated by the tool or material employed. When their resemblance to nature struck the primitive artist, he did what he could to make it closer, but they arose at first independently. A single stroke of a full brush on paper, beginning with a point, spreading from that, and then ending with a sudden and more rounded diminution as the brush quits the paper, resembles the form of a leaf; the simplest combination of such touches suggest a leaf-cluster. Surround a large circle with a series of little ones, and you get a broad hint of a frequent flower type. So our window maker, having advanced thus far, could not fail to be struck with hints of natural form in his pattern, and suddenly his brain took fire longing to complete the resemblance. This led to an application to transparent glass of the long-practised process of enameling; lines and shadnws were drawn on it with a material that, when fired at a sufficient heat, unites with the glass and becomes permanently fixed. The imitation of form seldom goes far in any art before the designer tries to imitate the most interesting of all forms: to take on him the God-like function of making man in his own image.

* H. Arthur Kennedy in the *Journal of the Society of Arts.*
* "Every-day Art," by Lewis F. Day.

FRIEZES.

WE must refer to the differences in mural ceiling designs, to the circumstance that there are friezes that look well in lighter tints than the wall color; but the general practice is to have the coloring stronger than the latter. One rule applies to either mode, and that is, that the forms should be distinct, however vague the general wall design. Where the general hue of the frieze is lighter than the former, a few touches of bright color will often restore a balance. It was a true burst of artistic taste that led to the present depth of friezes instead of scrimping bands. It is here worth noting that the proportions followed by the Romans and illustrated at Pompeii allotted one part of the height of wall to dado, three parts to the field and one and a half to the frieze, proportions adapted to the heavy Roman architecture. Where the mouldings of a room are unusually heavy, we have known decorators to introduce grey and light-some friezes of a more than ordinary depth, to lessen the too heavy effect. The fault of dull and dark friezes is being steadily corrected. It is usually better that the field and frieze should not wholly correspond in color, but the ground of frieze may be the same if of a deeper color than the fold.—*Beck's Journal of Decorative Art.*

A new effect in color in wall decoration was devised by Whistler in the painting of a small room. The walls were first painted a pure black, which was afterwards overlaid with a coat of semi-transparent yellow. The effect was the apparent annihilation of the walls and the production of the impression of living in a petrified nocturne, an endless London fog, but the small room no longer looked small.—*Plumber and Decorator.*

The tendency toward light colors in house painting and decorating, both inside and out, is very marked, showing a complete revulson of feeling against the dark and rich colors which were so popular a short time since. Even in city houses, where the trimmings and sash were almost altogether red, green or brown, these colors are now rarely seen, and the more common effects are obtained from combinations of buff, ivory or cream white, and the various delicate gray tints. These changes have affected the demand for paper-hangings and curtain stuffs, which now tend altogether to light backgrounds and delicate treatment, very generally floral in pattern, or perhaps plain tints not darker than a gendarme blue or an an old gold as an extreme limit.

Mr. William Kennedy, Newmarket, Ont., has been granted a patent for a hot water heater.

The wickedness of plumbers is always a favorite theme and is likewise a very suggestive subject, as witness the latest information that when a plumber was pitched out of a fifth floor window by his employer he charged double time from the moment he left the window till he struck the pavement.—*British Architect.*

We learn from the *Brickmaker* that Boston architects are beginning to think that it is desirable to break the monotony which steady rows of red brick buildings have, by introducing brick of other colors. It is surprising to see how many of Boston's newer buildings are of tinted brick. It is somewhat more expensive, since the clay pits about Boston all produce a red brick; but with cheapening rates of transportation the city is likely to use more brick from a distance. Instead of freighting the brick from the place of their manufacture, the clay itself is now being shipped to some kilns near the city, and there baked. A striking edifice in yellow brick will be the new building at Tufts College. The yellow brick will not turn, and the mortar will not whitewash, and the yellow brick is believed to harmonize better with the landscape than the standard red.

CANADIAN ARCHITECT AND BUILDER.

VOL. IV.—No. XI. TORONTO AND MONTREAL, CANADA, NOVEMBER, 1891. PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),

PUBLISHED ON THE THIRD SATURDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

14 King Street West, - TORONTO, CANADA.

64 TEMPLE BUILDING, MONTREAL.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1891.

ALPH. RAZA	Montreal.
J. E. PEACHY	Quebec.

IT is announced that the Province of British Columbia will be represented at the World's Fair by a building composed of every variety of wood that grows in her forests, adorned with ferns and mosses grown within her boundaries.

THE architect and decorator desirous of learning how to secure the most pleasing color effects, might profitably have spent a few of the latter days of October in studying autumn foliage in its unusually varied and brilliant aspects.

WE have been informed that previous to the publication of the October number of the ARCHITECT AND BUILDER, a misapprehension existed in the minds of many as to who was the author of the design of St. Paul's Episcopal Church, Toronto. We are pleased to know that unwittingly we were the means of removing this misconception, and of placing the credit of the design where it properly belongs.

WE would like to point out to the late secretary of the Toronto Architectural Sketch Club, who is now a resident of the "Ambitious City," a worthy object of ambition. It is that he seek to establish among the architectural students of Hamilton an organization similar to those now existing in Toronto and Montreal. There should be sufficient material available for the purpose, and Mr. Bond's enthusiasm and ability might be depended on to do the rest.

MUCH loss is said to have been caused the builders of Winnipeg by a recent strike of union plumbers. A local paper states that the employers signed an agreement to pay journeymen $4 per day after the 1st of August last, but when the time came, they claimed to be unable to carry out their promise on account of one shop in the city employing unqualified workmen at low wages. If this is the only reason the employers have to offer for the non-fulfilment of their written agreement, we unhesitatingly say that it is not a justifiable one.

THE Inspector of Buildings and the chief of the fire brigade have recently been engaged in making an examination of the public buildings of Toronto, with a view to determining whether sufficient means of exit exist. Their report has not yet been published, but, from private sources it is learned that some buildings in which large congregations of visitors daily assemble, have been found to be dangerous in this particular. The last inspection of this kind took place in 1879. The public safety demands that for the future such inspection should be conducted at more frequent intervals.

RIGHTEOUS indignation has been aroused at the action of the Consumers' Gas Co. in tearing up the asphalt pavement recently constructed on Bay St., Toronto, for the purpose of laying mains on the intersecting street. Citizens were under the impression that no interference with permanent pavements of this character would be allowed, otherwise they would not have consented to be heavily taxed for the improvement. The large sums spent of late on asphalt pavements in Montreal and Toronto will prove to have been wasted if corporations of any kind are allowed to break up the roadway. Heavy penalties should follow any future attempts in this direction.

A GOOD report reaches us from Hamilton concerning the plumbers of that city, to the effect that their work is of a uniformly higher grade than can be found in most of the cities on this continent. However this may be, some work which we recently had the opportunity to examine in houses of moderate cost in that city, is certainly very creditable, while the materials and fittings used are of a substantial character and superior finish. There can be no doubt about the wisdom of sacrificing, if need be, exterior ornamentation for the purpose of making a house as perfect as possible in its sanitary appointments. We are informed that Hamilton has become too warm a place for the "skin plumber" to make a living in, and that in consequence the architects feel that they can entrust their work to any of the existing firms with confidence that it will be carried out as satisfactorily by one as by another. This must be admitted to be a gratifying condition of affairs.

IN the present number of the CANADIAN ARCHITECT AND BUILDER is commenced the publication of a series of short biographical sketches of the City Engineers of the most important Canadian cities. The problems which the City Engineer of modern times is called upon to solve, demand that he should represent the highest ability in his profession. It is expected that the majority of our readers will be interested in knowing something about the gentlemen who occupy this important position, and the history of their successful efforts should prove an incentive to young men entering upon their career.

SCARCELY a week passes during the building season that is not marked by serious injury or loss of life by reason of defective scaffolds. It is unfortunately true that the responsibility for most of these accidents rests with the workmen themselves rather than with their employers, and for this very reason it is impossible to guard against their recurrence. The workmen themselves construct the scaffolds, and should see that in point of material and construction they possess the necessary margin of safety. Reckless overloading of scaffolds has probably led to most of the accidents. Workmen are justified in refusing to venture upon a scaffold which they have reason to fear is too weak to support the strain to be put upon it. Difficulty is often experienced, however, in inducing them to exercise necessary caution in this direction.

AN article headed "Who is the Rumper and Where does Rumping Start?" appears in the *Monthly Circular* of the Stone Cutters' Association of North America, over the name of Albert Phillips, of Toronto. Mr. Phillips places the man who does more work than the average man, in a worse category than the so-called "scab," "copperhead," and "snake-in-the-grass" who works for under pay. He says: "How often do we hear the remark made 'Bill spoiled this yard; it used to be a good, easy shop, before he came.'" To prevent other workmen from following Bill's bad example of working too fast, Mr. Phillips advises: "Keep your place, and consider it two bats behind." From the above, may the inference not fairly be drawn that the teaching of unionism is that it is the duty of its members to carefully guard against outstripping the efforts of the *average* workman, while at the same time endeavoring on all occasions to secure an advance in wages. This is, we take it, the meaning of "keeping two bats behind," and the reference to the "good, easy shop." It is another method of enforcing the unreasonable demand that all workmen must be paid the same wages, irrespective of their earning capacity. The workman is held to be worthy of being despised who exhibits any ambition to excel. The idea is one which, if attempted to be carried out in all branches of human industry, would speedily put a stop to the world's progress.

THE Toronto Architectural Sketch Club may properly be said to have been a successful organization from the outset, nevertheless its promoters think that in some respects it is open to improvement, and they are laboring earnestly to bring it up to a higher standard of perfection and of usefulness. New and more commodious quarters have been procured, and the work for the coming winter has been entered upon in a spirit which bids fair to result most satisfactorily. Prof. Wright, of the School of Architecture, has very kindly offered to conduct the classes in mathematics, and Mr. John Kiely, the classes in modelling. These classes will meet alternately on Tuesday and Thursday evenings of each week, and are certain to be the means of affording much valuable instruction in these important branches of knowledge. The officers have also been successful in arranging a series of lectures by gentlemen of recognized experience in the building trades on a variety of subjects pertaining to building construction. Thus means have been provided for students to make rapid advancement in the knowledge required in the practice of their profession. It remains for them to properly improve the opportunities thus placed within their reach. It is gratifying to learn that the Club starts the season with a largely increased membership. The officers elect may, we think, be relied upon to put forth every effort to make the future of the Club increasingly prosperous, and if properly supported by the members, they will no doubt succeed.

A CERTAIN class of real estate owners appear to be always on the look-out to take advantage of municipal authorities. If a public improvement is proposed, and any portion of their property is required for the purpose, they immediately place an exorbitant price upon it. The slightest pretext is made use of to prefer claims for damages. The action of such persons has frequently been the means of blocking public improvements, and in some cases the municipality, and indirectly the citizens, has thereby suffered great inconvenience and loss. In view of this, we note with satisfaction an instance which occurred in Toronto recently, wherein the tables were turned and the biter bitten. A certain speculative land owner some months ago brought suit against the city, claiming heavy damages on account of the construction of a sewer through his property, and to the public surprise, was awarded the sum of $35,000. The city authorities thought their best course would be to purchase the land outright and convert it into a public park. The owner was asked to state a price, which he did, but the amount, $74,000, was considered so exorbitant that the idea of purchase was abandoned. A week or two ago, the owner was surprised to learn that the assessment on this land had been appealed against by the City Solicitor on the ground of undervaluation. The City Solicitor insists that the property shall be assessed at the valuation put upon it by the owner, which would seem to be a reasonable enough proposition, although the latter indignantly refuses to view it in this light, which may be taken as proof of the old saying, that "circumstances alter cases."

THE builders and contractors of the Australasian colonies have determined to adopt the British system of basing their tenders upon Bills of Quantities prepared by competent quantity surveyors. The tendency in this direction is becoming very marked in the United States also. In Canada the uniform basis of tendering is perhaps as urgently required as in any other part of the world, but as yet no steps have been taken to obtain it. The *Australian Builder* describes the English method as follows:—"In London the Quantities are usually taken out by a quantity surveyor (or firm) appointed by the architect, and responsible for the accuracy of such Quantities. In large and important jobs two independent surveyors usually are appointed and work together, sharing the commission between them, by which the risk of error is reduced to a minimum. The Quantities are then lithographed along with the Specification, before tenders are called for. The lithographed Bills of Quantities and Specification are supplied together to tenderers, and the former bear, after the first Total, on the Summary of Trades sheet, the words, "Surveyors' Commission on the above (so much) per cent.", left blank. This, every tenderer fills in, in order to arrive at the gross amount of his legitimate *estimate* (which may, or may not, form the amount of his actual *tender*), and the successful tenderer pays the surveyor out of the first cash instalment he receives upon his contract. The tenderer, as a rule knows nothing as to who takes out the Quantities, until they are taken out and lithographed, and tenders are called for. We know of no practice or proposal more thoroughly equitable and satisfactory to all parties than this."

AN enterprising firm of architects in Montreal have opened a school for architectural students. We are not aware what subjects are taught that would assist students to gain a knowledge of architecture, but are informed that nothing in the shape of practical teaching relating to building construction is imparted. At a meeting of members and student associates of the Province of Quebec Association of Architects recently held for the purpose of listening to a paper on "Architectural Training" by Mr. Hutchison, a representative of this firm appeared and proceeded to advertise the merits of his school. In view of the fact that the Quebec Association had appointed a committee of its members to report on the institution of classes and lectures for the instruction of students who should become members of the Association, this action must be regarded as a somewhat presumptious one. It is surprising that the Association should have permitted it. It is still more surprising that some of the members should actually have opposed the proposition for the formation of classes and deliverance of lectures under the auspices of the Association, notwithstanding other members had volunteered to place their time and talent at the disposal of the students for this purpose. They surely must have overlooked the fact that they were aiming a serious blow at the prosperity of the Association, while working into the hands of those interested in preventing instruction being afforded the students by the Association. We are informed that the private school referred to, gives instruction in the French language only, and thus, no matter what may be its advantages to the French student, it is of no service to many students who are unfamiliar therewith. We were of the opinion that the education of students by means of classes, lectures, &c., was one of the most important of the objects which the Association was designed to accomplish. The fact ought at least to be apparent that the Association cannot hope to build up a successful future if it disregards the interests of the students. If the idea of affording instruction to students is abandoned, one of the strongest inducements which could be held out to them to become members will have been taken away. We hope that those who have at heart the present and future welfare of the Association will see the wisdom and necessity of making it a source of benefit to the rising generation of architects, and thereby rallying them to its support.

CARVED WOOD CAPITALS, ST. ALBAN'S CATHEDRAL, TORONTO.—EXECUTED BY THOS. MOWBRAY, TORONTO—R. C. WINDEVER & SON, ARCHITECTS, TORONTO.

PROPOSED NEW DRILL HALL, TORONTO.—THOS. FULLER, DEPT. OF PUBLIC WORKS, OTTAWA, ARCHITECT.

"ALPHONSO BLOCK," VICTORIA ST., TORONTO.—DICK & WICKSON, ARCHITECTS.

The Rathbun Co., of Deseronto, Ont., recently shipped a carload of doors and window sashes to South Africa.

Mr. C. S. Nellis, from the headquarters of the Adamant Manufacturing Co., Syracuse, N. Y., is at present making a tour of the Dominion in the interests of the Toronto Branch of the business.

HOW TO ESTIMATE.

By WM. H. HODGSON, ARCHITECT.

IN pursuance of the announcement made to contractors in the CANADIAN ARCHITECT AND BUILDER for October, I present to the reader the first of a series of articles designed to instruct the contractor in the method of preparing estimates on an accurate basis. The quantities herewith furnished have been taken with the greatest care and accuracy from the accompanying design and specification for a residence, and consequently are reliable. They give the actual materials in the building when completed, and the method by which the quantities have been arrived at. No allowance has been made for what is termed "waste"; this has to be considered by the contractor in his pricing of the several works. No attempt has been made to affix prices, as these vary so widely in different localities. The contractor should be familiar with prices in his own locality. The adoption of this system would place all contractors on equal footing so far as the preparation of their tenders is concerned, and would do away with all guess-work:

SPECIFICATION.

EXCAVATOR, MASON AND BRICKLAYER.

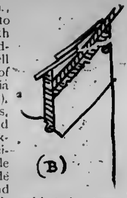
Excavate the ground as required for the cellars, and foundation of walls, chimney breasts, glazed pipe drains, etc. All vegetable mould to be put to one side for future use as directed. Fill in and ram and use the superfluous earth in terracing and leveling the lot, or cart away, as may be directed. The excavation to be 9 in. larger on all sides than the building, and no filling to be done till the stone walls are plastered outside and inspected. The drains marked G. P. on plans to be executed in with the best vitrified salt glazed pipe (Scotch or American), laid to proper fall as may be directed, jointed in cement, with all necessary bends, junctions and traps complete. Connect with sewer in street, contractor paying all fees. Put McGuire's cleaning out trap as shown, pipe from same to be carried to within 18" of surface and covered with stone flag. (All sewage drains inside of building will be of iron as per plumbers' specifications.) Lay 3" common tile weeping drains as shown properly graded and connected to main drains behind running traps as shown. Foundation walls to have footings of broad, flat stone 6" thick, projecting 4" on each side of wall above, and no stone to be less than half the total width of footing. The walls to be carried up to the height shown in good rubble masonry, composed of lake or other approved stone of the best quality, laid in the best prepared mortar, well built and bonded together, and having the joints on each side neatly struck with the trowel; the portion showing above ground and where lined is to be of brown Credit Valley courses in stone, neatly tape pointed in brown mortar, and having one border to at least every superficial yard of wall. The jambs to be tooth chiselled and to show a narrow draft on outer face. Plaster or parge outside of foundation walls from footings to finished ground line with ½ Portland cement mortar. None but hard bricks will be allowed on the premises. Brick walls in basement to be built of hard clinker bricks, with a neat struck joint. Build in all brick walls in basement a double course of roofing slate on top of footings 1" wider than wall to prevent rising of damp. Pier carrying front steps to be of hard clinker bricks on stone footings. The walls from underside of plinth to be carried up in brickwork of best hard, well-burned bricks laid in best prepared mortar. Projecting bays to be tied to main walls at every 5th course with stout hoop iron bond carried well into walls. Provide four (4) wrought iron straps 2"x¼" to be forked and built into brickwork, and well spiked to studding of front where prepared for tiles. The walls to be faced with the very best selected Carlton or other equally approved red bricks, selected of dark color, true and straight, laid in English bond, and finished carefully with a bead tool joint in mortar colored with Cabot's or other equally approved dark brown mortar stain; bricks to be well wetted. On completion of gutters, thoroughly clean down with acid. Inside walls of back ponds to be faced with white bricks finished with neat bead tool joint. Turn relieving arches of at least two rings over all openings of doors, windows, &c., and neat cut, and pointed arches at openings as shown. Build in strips for battens at every 2 feet in height in all outer walls and wherever else directed—strips to be provided by the carpenter. Beam fill on all walls to underside of floor and roof boarding, making all spaces thoroughly tight and weather proof. Turn proper arches over fire place openings on 2½"x½" wro't iron chamber bar, all flues to be formed circular 9" diameter, carefully built round moulds 3 ft. long, which are to be drawn up a few inches at a time as the work proceeds. Provide and build in proper galvanized iron collars to one flue in each room, (except those having fire places). Flues not connected with fireplaces to have proper iron soot doors in iron frames. Form ash dumps from ground floor fireplaces as shown, having iron soot doors set in cast iron frames. Leave 9"x12" opening into vent flue near ceiling of kitchen, and 9" diameter into same flue near ceiling of bath room. Chimneys to be carried up in brickwork of uniform color with projecting courses for caps. Bed in mortar all bond timbers, plates, etc., and build in all lintels, wood bricks, frames, cut stone and other work required to be set in masonry or brickwork. Support foot of iron soil pipes with 9"x9" brick pier, three courses high. Form substratum of concrete floor with a 6" layer of clean broken stone chips, pounded flat and level. The entire cellar floor to be laid in concrete 3" thick, of Portland cement, sharp sand and coarse gravel in proper proportion, and all but laundry and back porch floated to a smooth surface with a coating of Portland cement and sand ½" thick. Laundry and porch joists will be bedded in concrete. All hearths to have 4½ brick trimmer arches and to be of concrete as specified for cellar floors. Finished hearths will be of tile provided by the proprietor. Brickwork to be built from outside scaffolding which is to be left for the use of other trades till directed to be removed by the architects, special care being taken to prevent walls being splashed from scaffolding. The labels and strings where shown to be one course of plinth brick, set thus: (A).

(A)

Provide and set sills of Credit Valley stone to basement windows, to be 6"x9" and weathered; fuel doors will have wood sills. The sills to all other windows as tinted brown to be executed in the best quality of Portage Entry stone, or other approved brown stone, throated, chiselled or rock faced, weathered and seated; rear sills may be of Ohio stone. Heads of fuel doors to be of brown stone 9" high. Head of entrance door to be of Portage Entry stone, 1½ bricks thick, cross tooth chiselled. Corbels at front pilasters to be of similar stone similarly finished. Carefully set in fine mortar and protect with boarding till the completion of the work. Bricklayer to attend on other trades in the execution and for the perfect completion of the work.

CARPENTER AND JOINER.

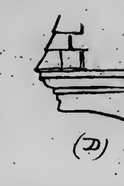
The lumber for the carpenters' [illegible] good description of w[illegible] pine thoroughly seasoned, free from sap, shakes, loose or large knots, or other imperfections, and to hold the full sizes shown or specified, when fixed in the building; good sound seasoned hemlock may be used for joists and rafters. The joiner's work (unless otherwise specified) to be of best description of white pine, clear and thoroughly seasoned. Inside work on ground and first floor will be varnished. Provide and fix all necessary centrings and turning pieces to openings of doors and where required. Provide and fix lintels to all openings of doors and windows, cambered at top, and not less than 6" in depth at centre, and resting 6" on walls on each side. Provide straps 2½"x¾" to be built into walls under bearings of joists and elsewhere as required for fixing skirtings, trimmings of doors, windows, etc., and other finishings, and at every 2 feet in height of outer walls, on which to nail battens. Batten all outer walls, (including attic where necessary) and elsewhere as required with 2"x1¼" battens, at 16" centres—battens not to be placed till walls are parged. Porches will not be plastered. Provide proper grounds for fixing trimmings, etc. Cellar floors of laundry and porch to have 3"x4" cedar joists bedded in concrete. Ground, first and attic floor joists to be 10"x2" at 16" centres properly trimmed at fire places, wells of stairs, etc., trimmers to be 4" thick or double 2" and framed with double tenons. Put a tier of 2"x2" herring bone strutting to each bearing of joists on all floors. Prepare floors for pugging at gables where projecting beyond wall line with one inch boarding. Sloping roofs, 6"x2" rafters, at 16 centres, and valleys 8 in. x 3 in., plates 9 in. x 3 in., collars 6 in. x 2 in. at 16 in. centres. Ends of rafters to be dressed where visible. Sloping roofs to be laid with dressed ¾ in. matched boarding in widths not exceeding 7 in., free from loose knots, shakes, or sap, well nailed. Put saddles behind chimneys boarded as roof and 3 in. rounded roll to ridges. Put dressed facia and 1 in. beaded soffit to eaves, and bed moulding. (B).



(B)

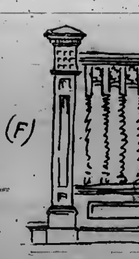
Gables to be 4 in. of studding at 18 in. centres, sheeted both sides with narrow matched stuff and lined on inside before battening with a double thickness of sheathing paper well lapped; batten as specified for other walls, sheet soffits with narrow, double beaded stuff matched on double sheathing paper made close and tight at walls, etc., and (C) form eaves and bed mouldings, as shown. Beams and corbels at side gable to be dressed and moulded as shown. Front gables to have dentil moulded large boards, as shown, (D), secured in strongest manner. Roof of rear porch to have

(C)



(D)

dressed rafters, and 1½ in. matched and beaded dressed roof boarding. Partitions to have heads, sills and braces 4 in. x 3 in.; door studs 4 in. x 4 in., or double 4 in. x 2 in.; common studs 4 in. x 2 in., 16 in. centres, all to be properly framed and cross-braced, those carrying joists or rafters to have heads 3 in. x 4 in., and upper studs to be carried down to them and to be well braced. Studs to be placed on flat in confined places. The ground and first floors to be laid with ⅞ in. dressed, tongued and grooved seasoned flooring of the best quality, in boards not exceeding 3½ in. in width, blind nailed to joists, and properly cleaned off on completion; attic and basement, (where called for) to be laid with ⅞ in. matched flooring of good quality, in boards not exceeding 5 in. in width. Floors in attic to extend to wall line. Ground and first floors to be laid on thicknessed 1 in. boarding laid diagonally with a double thickness of carpet felt between. Carpenters not to lay any floors till all gas or other pipes are put in, and finished floors not to be laid till completion of plastering. Put mitred margins to hearths. Main stairs to be built on 1¼ in. moulded strings, 1¾ in. wall strings to have 1¾ in. treads, rounded and returned nosings, cavetto and fillet and cut brackets, ⅞ in. risers, two 7 in. panelled and moulded newels at foot, and the rest 5 in. turned and moulded cherry newels, 3 in. x 3 in. moulded cherry handrail with 2 in. roll, and 2 in. turned pine balusters. Stairs to be built on proper carriages, well bracketed with 1 in. brackets nailed to each carriage under each step. Spandril at side of stair and forming enclosure to coat closet of 1⅜ in. framed and moulded panelling, all according to drawings; panelled door to closet under. End of stair facing entrance to have balustrade as shown. (F). Back stairs to have 3 in. rounded hardwood rail, 4 in. hardwood newels, and square balusters, to have 1¾ in. treads, rounded and returned nosings and scotia ⅞ in. risers, put together in the best manner, with 1¾ in. wall strings. Stairs to cellar to have close strings, 2 in. treads, 3 in. rounded rail, 4 in. x 4 in. chamfered newels. The kitchen, back stairs and pantries to be sheeted with ⅞ in. matched and beaded sheeting 3 ft. high, and bath room 5 ft. high, blind nailed to proper grounds, and finished with moulded capping; boards not to exceed 4 in. in width, except in bath room, where they will not exceed 2½ and to be double beaded or moulded. Drawing and dining rooms, hall, vestibule and staircase to have 10 in. double facia moulded skirtings, and the rooms and hall on first floor 9 in. single facia ⅞ in. thick, all properly scribed to floors and nailed to proper grounds. Nail fillet to floor at base. Base in attic 7 in. torus. Trim at registers and cut for plumbers, and hot air pipes. Put ⅞ in. staff beads to all projecting angles in kitchen and attic. Bracket down for plaster arches on ground floor and first floor, as shown by dotted lines, bracket down for drawing room. The cellar windows (except where otherwise specified to [illegible] x 4 in. solid rebate upon chamfered frames, 1¾ in. sash [illegible] Elsewhere [illegible] -sent tim



(F)

hung at top with 3 in. butts, and to be furnished with iron water-bars, 4 in. barrel bolts and hooks to hold them open. Cold air inlet to be protected with stout wire having ¼ in. mesh and well secured. Fuel doors to have 2 in. oak sills, to be 1¾ in. panelled and prepared with stops for glazing, hung at top and furnished with hooks and 6 in. bolts. The whole of the windows above cellar (except where otherwise specified) to have proper boxed frames, 2 in. double sunk sills, outside hangings of stiles, 1¾ in. moulded sashes hung with the best sash cord over the best iron axle pulleys. Front drawing room window to have boxed head, fixed fanlight, moulded transom as shown. Four (4) windows on front elevation to have 2⅜ in. sashes with stops in preparation for plate glass. Windows to be fastened with approved fasteners of the value of $4.50 per doz., and furnished with best bronze window lifts. Bed room windows, first floor, front elevation, to have simple, moulded pilasters, sills, heads and transoms as shown, fanlights to be fixed and prepared with stops for lead glazing. Short window at first main stair landing, and that in linen closet, to have solid rebated frames, with stops for lead work. Windows in coat closet under main stairs, and side windows in attic to have casement sash with drip and water bar, properly hinged, to have knobs, and secured with brass bolts. Dormers to be according to details and to have casement sash with drip and water bar, to be properly hung and fastened with spring catches and brass bolt. Fit to four windows in west elevation 1⅜ in. outside venetians properly hung and fastened. Prepare four windows in front elevation for Willer sliding blinds with all necessary stops, fillets, blocks, etc., complete. That on ground floor will be made to slide in pockets, behind window back, and covered with hinged flap. Entrance door to have 6 in. x 4 in. rebated and moulded frame, 2 in. staff bead, and 2 in. rounded oak sill, door to be 2⅜ in. oak veneered on outside, panelled and moulded and prepared with mouldings above for glazing, to be hung with three 5 in. loose butt bronze hinges, and furnished with hall door lock of the value of $4, and having 2½ in. bronze knobs. Vestibule doors to be 2½ in. panelled and moulded below, and prepared with mouldings above for glass, doors hung in rebated and moulded jambs with three pairs of 4 in. loose butt bronze hinges, and furnished with 4 in. American rebate mortice locks, brass bolts, keys, bronze knobs and furniture, 9 in. bronze flush bolts. Back porch door to be 1¾ panelled and bead flush, hung on 6 in. x 3 in. rebated and chamfered jambs, having 2 in. oak sill, to be properly hung and furnished with Carpenters' rim lock, white furniture and 8 in. barrel bolts, hinged and bolted fanlight. Side porch door to be similar, but to have hall door lock of the value of $2, porcelain and plated furniture. The doors to the two principal floors to be 1¾ panelled and moulded and hung to 1¾ in. rebated jambs. Doors to principal rooms, ground floor, to be hung and furnished as specified for vestibule doors, those to first floor to be hung with 4 in. loose butt Berlin bronze hinges and furnished with 4 in. American mortise locks, brass bolts and keys, and porcelain and plated furniture. Sliding doors to have proper overhead track, and to be furnished with Clarke's patent hangers, and with sliding door lock and flush handles. The other doors throughout (unless otherwise specified) to be 1⅜ in. panelled and moulded, hung with 4 in. loose butts to 1⅜ in. loose jambs, and furnished with American mortise locks, brass bolts and porcelain and plated furniture, two doors in attic to have pivoted fanlights. Closet doors to be 1⅜ moulded one side, furnished with locks and furniture to correspond with other doors. Doors marked "swing" to be 1¾ in. thick hung with nickle plated, Chicago spring hinges, and furnished with porcelain finger plates, both sides, and brass bolts. Opening marked "curtains" will not have doors but to be prepared for them, with rebated jambs, casings, etc. Doors in basement to be 1⅜ in. batten in 1⅜ in. jambs, having stops planted on, hung with 4 in. butts, and furnished with rim locks and mineral furniture. Architraves on ground floor main building to be 5½ in. double faced with hand moulding. Architraves on first floor to be similar 4½ in. wide. Architraves in small rooms, passages, kitchen, attic, etc., to be 4 in. moulded with plain chamfered blocks. Put 2½ in. picture mould at spring of cove in drawing room. Window, except those to two principal rooms, ground floor, to have 1½ in. moulded window boards, bed moulds and moulded aprons. Windows of drawing and dining rooms to have panelled and moulded window backs. Front steps to have turned newals, moulded rail and balustrade as shown, treads to be 1¾ in. and slatted. Kitchen pantry to be fitted up with six tiers of 1 in. dressed and beaded shelving supported on proper bearings. Fit up dressers in kitchen and service pantry, having 1½ in. panelled and moulded doors, properly hung and fastened, ⅞ in. beaded shelving—lower portion to be wider and to have drawers and cupboards below, having properly hinged and fastened doors, all according to detail; top of wider portion of dresser will be flush with top of sink, and to be of hardwood grooved for drainer. Bed room closets to have beaded shelves as shown, 5 in. beaded rail and strong bronzed metal hooks, 9 in. apart. About 30 feet of beaded rail with hooks 9 in. apart, to be placed where directed, also 100 feet of shelving on bearers, all in addition to that specified for closets. Hanging shelf in larder to be of 1⅜ in. stuff, suspended from ceiling with four ½ in. wrought iron rods. Fit up two tiers of 1½ in. shelving at each end of larder on proper supports. Linen closet to have wide shelves six in height, at ends, and enclose those at one end with hinged cedar fronts, fastened with spring catches. The steps in back porch to be of pine 1¾ in. treads, 1 in. risers, 2 in. strings, rounded rail, bar balusters and chamfered newels. Fit up stands for kitchen and cellar sinks with hardwood capping. Do all necessary attendance and fitting for bath, basin and water closets (not including plumbers' work). Case plumbers' work where required with narrow sheeting hinged and bolted at front. The capping of bath and lids and seats of w. c.'s to be of cherry, the latter supported on moulded brackets; w. c.'s to have double lids for slop sink. Front of bath to be of same sheeting as specified for room; panelled, hinged and bolted doors to front of basin. Provide all necessary boxing and beaded runs to pipes; do any necessary cutting for plumber. W. c. in cellar to be enclosed with sheeting, and batten door, and hung and furnished as other basement doors. Door to be kept 6 in. from floor and ceiling. Borrewed light as shown. Put 2 in. planking in yard at doorway as shown, on 4 in. x 4 in. cedar sleepers. Form slatted walks as shown with 2 in. x 2½ in. dressed stuff, dressed three sides, on 4 in. x 3 in. cedar sleepers; put rounded curb at edges of that to main entrance. Put side gate as shown, formed with narrow pickets, and strong framing, hung with strong T hinges and furnished with wrought iron thumb latch, bolt and padlock, dressed and rounded cedar posts, footed, and having chamfered head piece. Erect short piece of picket fence 6 feet high, on south side to harmonize with gate, also a short piece on north side of porch. Fuel bins to be constructed of 2 in. horizontal planking, strongly nailed to 4 in. x 4 in. posts extending from floor to ceiling; the front to be made to slide in grooves for removal if necessary. Construct cold and fresh air duets of dry 1 in. matched stuff with hinged valve, which will close inlet from floor when opening that from outside. Carpenter to attend on other trades in the execution and for the perfect completion of the work.

SLATER.

Line valleys with galvanized iron 15 in. wide, increasing to 18 in. near foot. Joints to be soldered where in danger of snow backing up water, and to have 4 in. lap in other place. Cover ridges, etc., with No. 28 iron. Step and cloak flash against all walls, chimneys and checks and apron of dormer. Put strip of galvanized iron 5 in. wide, 3 in. on roof and 2 in. drip over back of gutter, well secured. Cover flat of cornice over three windows on first floor with galvanized iron, lapped, tacked and soldered, and turned up 6 in. behind tiling. Cover the sloping roof, including back porch and cheeks of dormer, with best quality of Canadian roofing slate from the Rockland quarries of about 20 in. x 11 in. size, and having double courses at eaves. Slates to be laid on heavy felt provided and laid by slater. All exposed portions of dormer to be carefully covered with felt well lapped. Cover east and south gables as shown with Daney's, Ontario, or other equally approved tiles, of good rich, dark red color, well secured to walls, and laid on heavy felt, well lapped and tacked.

TINSMITH.

Put 4 in. eave troughs of galvanized iron to eaves of back porch, and 5 in. do. to eaves of house of No. 28 guage iron. Gutters to be stiffened with 7-16 in. x 7-16 in. wro't iron bars and well secured to rafters, and to have backs carried up to slates. Put three (3) stacks of 4 in. octagon down pipes to house and one 3 in. to back porch, all to be of the very best iron, No. 28 gauge, approved brand, properly connected with gutters, secured to walls with iron holdfasts, and extending to surface of ground and there connected with drain pipes with proper caps to pipes. Carry 3 in. down pipes from gutters on south gable to main eaves.

PLUMBER AND GAS FITTER.

Lay on through house best tested iron piping, beginning with 1¼ in. at meter, and connected with various points marked on plans with letters P for pendents and B for brackets, nipples left capped ready for fixtures. Pipes to diminish according to position to 1 in., ¾ in. and ½ in., all to be thoroughly tested. Drop lights to be taken out of the side of supplies and all supplies to brackets to rise from supply below, and in no case to drop from pipes overhead. Lay on separate supply from separate meter, to two fire-places on ground floor and to gas-stove in kitchen, beginning with ¾ in. and diminishing to ½ in. Provide cocks with keys at fire-places. Lay on water to sinks, bath, basin and water closets with ½ in. 6 lbs. lead supply. Service from street line to line of branches to fixtures to be ⅝ in. 8 lbs. lead. Provide hose connection at window of furnace room, with key cock, and provide stop and waste cock near floor. Put ¾ in. brass stop and waste cock immediately inside wall of house, and all pipes to be graded to this point. Fit up in bath room best No. 14 guage tinned and planished copper bath 6 ft. long, with ½ in. 6 lbs. lead, hot and cold supply, and best heavy plated Fuller double bath cocks, plated rose and 1½ in. overflow, 1½ in. waste, Dubois trap, and brass trap screw, and plated plug and chain. Wash basin of best marbled earthenware, oval, and having Moits standing waste, 1¼ in. counter sunk marble top, 1 in. back and end, 12 in. high, heavy plated Fuller cocks, ½ in. hot and cold lead supply and 1¼ in. lead waste, Dubois trap and brass tap screw. Basin to be attached to marble top by means of brass clamps. Provide and fit up on first floor an all porcelain flushing rim wash-out closet, equal in value to the Inodoro or Unitas, with lead lined tank, having brackets, valves, supply, overflow, ball cock, &c., complete. Provide porcelain drip tray. Soil pipe to be 4 in. of cast iron carried from drain 2 feet beyond wall to 4 feet above roof at point of exit and to down pipes at surface of ground, to be coated both sides with coal tar and joints carefully caulked with ohum and lead. Dig for these pipes and replace earth properly leveled, and cart away surplus if any. Pipe to be of weight called for in city by-law. Provide all necessary traps, and hand-holes, with brass cleaning screws as shown. Foot of soil pipe will be supported on brick pier built by mason. Carry 3 in. cast iron waste from kitchen sink along ceiling of cellar to main soil pipe, supported on wro't iron hangers. Carry a 3 in. cast iron vent pipe from basement closet connecting to soil-pipe above highest fixture (in bath room), and leave connections for vents from the various traps as required. The 4 in. soil pipe to be enlarged to 6 in. above roof line, and to have opening mouthed top. Carefully flash on to roof with 16 oz. copper, into hub which must be kept clear of roof. W. c. in basement to be a flushing rim, cane ware wash out with 4 in. trap, syphon, cistern, etc., complete. Ventilate from seat to special flue in laundry with 3 in. galvanized iron pipe. Put a 7 in. diameter enameled valve register in vent flue near ceiling of bathroom. Put a 9 in. x 12 in. enameled valve register near ceiling of kitchen into vent flue. Ventilate drain by means of a 4 in. cast iron pipe connected to drain and carried 2½ feet above finished ground line with return bend top. Put under bath and wash basin on first floor proper safes of 3 lbs. lead with ¾ in. waste, with brass flap valve on the same emptying over kitchen sink. Carry proper safes under all pipes crossing ceilings. Safe under w. c. on first floor to be of marble, 1¼ in. thick and counter sunk; put brass strainer on outlet of waste and connect to other safe wastes. Fit up in kitchen best galvanized iron sink 2 ft. 6 in. long, with brackets and enameled back and having 1¼ in. heavy lead waste with Dubois trap, and brass trap screws and hot and cold supply of ¾ in. lead pipe with brass Fuller cocks. Fit up in kitchen at back of stove on proper stand a heavy galvanized iron round topped cylinder of 40 gallons capacity, with ⅝ in. heavy lead hot and cold supply, ¾ in. brass connections with stove in kitchen with shut-off cock; connect to stove with 1 in. iron pipe. Cylinder to have ¾ in. sediment pipe and cock at bottom; also place ¾ in. stop cock on supply pipe. Boiler to be supplied from pressure; provide combined safe and vacuum valve. Fit up small cast iron sink in cellar, having 1½ in. lead waste, trapped and supplied as other sink. Overflow pipe from basin and bath to be branched into dip of traps from same. Make all necessary Y branches for work as required, all waste pipes to have vents of 1½ in. and 2 in. lead pipe, carried into 3 in. pipe before mentioned. Vents for w. c.'s to be 3 in. diameter. Prove and fix from hall near head of main stairs to kitchen a proper tin speaking tube, with silver plated mouth pieces, etc., complete. All to be left complete and perfect in every particular. All work to be in conformity with city by-laws.

PLASTERER.

Inner face of all outside walls, including attics, to be well rendered with best hair mortar after being built and before battening is executed, and make thoroughly tight also between all joists, etc., entering therein, also about all door and window frames. Floors at gable in attic to be deadened with mortar 1½ in. thick. Lath the partitions, ceilings, soffits of stairs and other places prepared for lathing, with the best sawn pine laths, 1 in. wide for ceilings and 1¼ in. for walls, 5-16 in. apart, ends butted and joints broken every 18 in. Outer walls will be battened for lathing. Porch will not be plastered. Plastering to be of the best two coat work hard white finish. The ceilings of cellars throughout to have two coats hard white finish. The first coat of plaster in all cases to be continued behind skirtings, trimmings, etc. Form slightly rounded corners to all projecting angles to principal rooms and hall on ground and first floors. Simple cove in drawing room springing from wooden picture mould. Plaster cornice in dining room to be 24 in. girth, in hall 20 in., and in vestibule 15 in. Put 2½ ft. moulded centres to dining and drawing rooms, and 18 in. diameter to hall. Form simple moulded beams in ground and first floors as shown by dotted lines. Twice lime whiten walls of cellars. The whole to be executed with the best description of material and workmanship, and to be left sound and perfect after making good after other trades. Plasterer to remove rubbish and broom out floors on completion. Leave woodwork clean and ready for painter.

PAINTER AND GLAZIER.

The whole of the internal and external dressed woodwork usually painted and except where otherwise specified, including outside steps and slatted walks, and dressed fence and gate to be painted three coats of white lead and linseed oil paint of approved tints. The work to be properly knotted and stopped, and well rubbed down after first and second coats. The woodwork of ground and first floors to be stained, oiled and twice varnished with best copal varnish. Treads and risers of main and back stairs to be stained and twice oiled. No inside blinds to be included in tender. Outside venetians to four rear windows to be painted three coats after priming. The visible galvanized iron work to be painted three coats. Except where otherwise specified, the whole of the windows and fanlights, glass doors, etc., to be glazed with double diamond star glass, selected free from flaws and defects, to be well puttied and back puttied, and bradded, the whole of the sashes to be primed before glazing. Glaze four windows on east elevation with ½ in. polished plate glass, and the small square lights of east windows in attic with rolled cathedral glass of selected tints. The glass in fuel doors to be ⅛ in. rough rolled plate secured with stops. Other glass in cellar to be diamond star. The two windows at staircase landings and fanlights of four windows in east elevation to be glazed with stained glass provided by proprietor. Glass in vestibule doors will be provided by proprietor. Glass in entrance door to ⅜ in. be polished plate, bevelled. Glass in fanlights as marked to be ground; glaze borrowed light in basement w.c. with ground diamond star glass. Clean windows, scrub floors before and after painting, and leave all clean and perfect on completion. Put in sashes when directed, and do any necessary re-glazing required.

EXCAVATION, DRAINAGE, ETC.

	$	c.
325 cubic yards of excavation, includes filling, levelling, etc., and carting away surplus earth		
6 lineal yards of 6 in. vitrified tile drains, complete		
5¾ lineal yards of 4 in. vitrified fresh air inlet, complete		
36½ lineal yards of 3 in. tile weeping drains		
1 McGuire's cleaning out trap, and stone flag covering, complete		

NOTE.—Excavations are measured "cube," that is, length, breadth and depth, thus: 54 ft. 9 in. x 22 ft. 6 in. x 5 ft. 6 in. = equal to 6775 ft. 4 in. divided by 27, the number of feet in a cubic yard, gives 251 cubic yards, less (1 ft. 8 in.). Tile drains are measured lineal, that is, running measure, as indicated in above items.

MASONRY AND CUT STONE.

	$	c.
29 toise of masonry (86 ft. cube English measure) in foundation walls, (parg-tted in cement outside)		
168 ft. 9 in supl. ft. Credit Valley cut stone base, inch draft and chiseled to jambs, complete		
4 Credit Valley stone sills, fine buchard, to cellar windows, 3 ft. 9 in. x 9 in. x 6 in., weathered		
1 Credit Valley stone sill, fine buchard. to cellar window, 3 ft. 3 in. x 9 in. x 6 in., weathered		
1 Credit Valley stone sill, fine buchard, to cellar window, 2 ft. 9 in. x 9 in. x 6 in., weathered		
1 portage entry stone sill, chiseled, to front window, 7 ft. 6 in. x 11 in. x 9 in., weathered and seated		
1 portage entry stone sill, chiseled, north window, 4 ft. 9 in. x 11 in. x 6 in., weathered and seated		
2 portage entry stone sills, chiseled, north and south windows, 4 ft. 0 in. x 11 in. x 6 in., weathered and seated		
7 portage entry stone sills, chiseled, north and south windows, 3 ft. 9 in. x 11 in. x 6 in., weathered and seated		
1 portage entry stone sill, chiseled, north and south window, 3 ft. 6 in. x 11 in. x 6 in., weathered and seated		
1 portage entry stone sill, chiseled, south window, 2 ft. 9 in. x 11 in. x 6 in., weathered and seated		
3 portage entry stone sills, chiseled, 2 ft. 0 in. x 11 in. x 6 in., weathered and seated		
3 Ohio stone sill, chiseled, rear windows, 4 ft. 0 in. x 11 in. x 6 in., weathered and seated		
1 Ohio stone sill, chiseled, 3 ft. 0 in. x 11 in. x 6 in., weathered and seated		
2 brown stone fine Bouchard heads to fuel doors, 3 ft. 0 in. x 9 in. x 9 in., checked for frames		
1 portage entry stone head to front doors, 7 ft. 0 in. x 13 in. x 14 in., chiseled and with curved sunk face		
2 portage entry corbels, curved face, 2 ft. 0 in. x 9 in. x 40 in., temporary protected with boards		
Bedding to frames, lintels, etc.		

NOTE.—Masonry is measured cube and the totals of dimensions added together, divided by 86, the number of cubic feet in a toise. The French measure per toise being 6 ft. x 6 ft. x 2 ft., equivalent to 6 ft. 4½ in. x 6 ft. 4½ in. x 2 ft. 1½ in. English measure, the French foot being ¼ of an inch longer than one foot English. Cut stone is measured superficial, that is, square, thus: 20 ft. x 20 ft. gives 400 superficial feet. Sills, heads, steps, etc., are counted and the number given according to sizes and quality of work, as shown in above items of quantities.

BRICKWORK.

	$	c.
7,648 hard clinker brick in cellar walls		
37,725 best hard common brick		
18,889 best Carlton facing brick, cleaned down with acid		
1,375 white brick, inside porch		
252 lineal feet of bevil and projecting bricks, labels, strings, etc.		
16 lineal feet of curved labels, strings, etc.		
77 lineal ft. of 2 rows slate on footings of brick walls, 20 in. wide		
100 lineal ft. of hoop iron for ties		
24 relieving arches		
6 curved arches (semi-circular and elliptic)		
4 fireplace arches on 2½ in. x ⅛ in. iron camber bars		
4 brick trimmer arches in concrete, to hearths		
8 circular flues (built round moulds) to chimneys		
4 wrought iron forked straps, 2 x ¼ in., and spikes		
7 galvanized iron collars to flues		
5 iron soot doors and frames to ash dumps and flues		
2 openings to vent flue, kitchen and bath room near ceiling		
3 chimney caps of projecting brick courses		
Bricklayer to build in strips for battens in outer walls and where directed, beam filling to doors and roof timbers, bed bond timbers, lintels, plates, wood bricks, frames, &c., and attendance on other trades		
Scaffolding on outside for brickwork (left for other trades)		
105 square yards of concrete, 3 in. thick, and substratum 6 in. thick, broken stone chips		
80½ square yards of Portland cement and sand, floated ½ in. thick		
Bedding, laundry and porch joists in cement		

NOTE.—Brickwork is measured cube and in Montreal the number of bricks given in estimating, is 20 bricks to the cube foot, and is ascertained thus:

6 bricks long say 4′ 0″
9 " high " 2′ 0″
54 8′ 0″ = divisor.
3 brick thick

8 | 162 | 20 to the foot.
16

The openings are measured and deducted from the solid work. Concrete when not deep is measured by the superficial yard, thus, 3 ft. x 3 ft. gives one yard. Concrete in heavy work is measured cube, 3 ft. x 3 ft. x 3 ft., or 27 feet to the cubic yard. Arches, etc., are given in numbers and other items noted as above.

ARCHITECTURAL TRAINING.

By A. C. HUTCHISON, R.C.A.

THE following paper on the above subject was read by the author at a meeting of architects and students of architecture held in the rooms of the Province of Quebec Association of Architects, Montreal, on Thursday, the 5th inst.:

I take it for granted that the object of architectural training is to properly qualify any person wishing to practice the profession of an architect by such a course of scientific and art instruction as will render him a competent architect. The question will at once arise, when can any architect be termed competent? I think the least that can be expected of any claiming to be competent is, that leaving aside any special skill that may be required in designing works of a monumental character or special technical knowledge required for designing a building for some novel or extraordinary use, he should be able to design a building for any ordinary purpose or situation so that its construction shall be safe and its appearance such that no violence shall be done to any canon of Art. For illustrating and working out of his design he should be able to prepare all the plans, elevations, sections, etc., as will make his intentions clear and to be understood by others. He should also be able to make a perspective drawing of any portion of his design, by which he can better illustrate his intentions to non-professionals who might not be able to appreciate them from the examination of geometrical drawings. He should also be able to prepare a specification in which the quality of materials, modes of construction and quality of workmanship are defined in such manner as to make his intentions clear to the workmen charged with the carrying of his design into execution. He should further be able to determine by an inspection of the work as it progresses whether his instructions are being carried out in a proper manner. To do this satisfactorily to himself and his client, he should by previous training be familiar with building materials and their use, and be able by a knowledge of construction to apply them in such manner that they are not wasted, and that his building is safe and perfectly able to fulfil the purpose for which it was intended. He should also have a knowledge of sanitary science, heating and ventilation, so that the building designed by him shall not only be comfortable to live in, but also free from anything prejudicial to health. In addition to this, he should have a general knowledge of the different styles of architecture, and such a definite knowledge of the styles or the style he adopts for his design as will enable him to apply it correctly.

I think it will be admitted that in the interests of the profession and of the public, a lower qualification than I have just indicated should not be entertained.

Before entering upon the question as to the character and scope of the scientific and art training necessary to qualify a person to become a competent architect and how such training can be obtained, let us briefly consider the position of the profession in the Dominion, its relations to the public and to the training required to qualify as an architect.

Until the obtaining of Acts of Incorporation from the Provincial Legislature by the Ontario Association of Architects some eighteen months ago, and still more recently by the Association of Architects for the Province of Quebec, there was nothing to prevent anyone, whether qualified or not qualified, from practising as an architect. In both of these Acts provision has been made for passing examinations before entering upon the study of architecture, and before entering upon active practice as an architect. The first or preliminary examination required by these Acts is to determine whether the candidate wishing to study architecture is qualified by his previous education to proceed upon such study; the second or final examination is to determine whether the candidate after completing his course of study has obtained such scientific and art knowledge as will qualify him to practice as an architect. As both of these Acts provide so many claims of a compulsory character, it is evident that a somewhat broader architectural training necessary to qualify for entering effect far more is one of vital importance, especially to those of the old methods entered upon or propose to enter upon the profession.

Heretofore and at the present time

ing such instruction is for a pupil to enter an architect's office, where, during three years pupilage, he is expected to acquire all the instruction and training required to qualify him to pass the final examinations required by the Association.

I think you will admit that the office work usually allotted to a student during his pupilage, while giving him a good training in practical work which could not be otherwise so well obtained, does not really afford the training in many subjects with which he should be familiar, the acquisition of knowledge in these subjects depending almost wholly upon his own diligence in the study of such works on architectural subjects as may be within his reach. When we consider the cost of architectural works, and the usually very limited means which an architect's student has for purchasing them, it is evident that his means for obtaining information in this way is somewhat limited, and unfortunately, it is to be regretted that the public libraries of Montreal do not contain the class of architectural works most useful to the student who might have the privilege of consulting them.

Until within a comparatively recent period, the same conditions as exist here for acquiring the training necessary to qualify for the practice of architecture existed elsewhere, but during the last thirty years many members of the profession in Britain, France, and the United States, have realized the fact that while the pupilage system has many advantages which cannot be ignored, it does not really afford a training in many subjects with which the student should be familiar if he expects to reach a high position in the profession.

It was probably owing to a realization of the defects of the pupilage system some thirty years ago by eminent members of the R.I.B.A., that an agitation was commenced for the establishment of a standard of qualification to which a candidate should attain before he was considered fit for practice as an architect, and that his fitness should be proved by passing examinations in prescribed subjects in the same manner as was required by the members of other professional bodies. The result of the agitation was, that the Institute prepared a scheme for voluntary examinations in subjects prescribed by them, the first of which took place in 1863. As the successful passing of the examinations under this scheme conferred no distinction upon the candidate, nor did it give him a position in the profession over those who did not attempt to qualify under the conditions, it is not surprising that the scheme, leading to no practical result, was in a great measure a failure, and the examinations carried out under it gradually languished. After a few years trial of the scheme, some modifications were made in it which had the effect for a time of giving it new life and bringing forward more candidates for voluntary examination. These modifications consisted principally in the dividing of the examinations into two classes, termed "preliminary," and "proficiency," and the granting of certificates to successful candidates with the title of "Graduates of the Institute," but still leaving them entirely voluntary. After the scheme thus modified had been in operation for some time, it was felt by many of the leading minds in the profession that though connection with the Institute as Associate had a very considerable value, it did not always give the holders of it the standing in the eyes of the public that they should have: it was, therefore, proposed some ten years ago, with a view to increase the value of the title A.R.I.B.A., to make the examinations compulsory on all future candidates for Associateship of the Institute. This proposal was, after considerable discussion, adopted, and a scheme of examinations prepared, the successful passing of which entitled the candidate to rank as an Associate; this scheme has now been in operation for about ten years.

The adoption of compulsory examinations by the Institute soon made it evident that a better system of training than was then in vogue was required to enable candidates to successfully pass them, consequently we find that in University College and Kings College, London, in which the study of architecture formed part of the regular course of instruction, modifications were made in their curriculums which better adapted them to furnish, if not the practical, at least the theoretical knowledge necessary to enable their students to pass the examinations fixed by the Institute. Besides these colleges there were a number of institutions of various kinds in London and elsewhere throughout Britain that offered pupils in architects offices an opportunity of obtaining instruction in subjects necessary to qualify for such examinations.

At this distance it would appear as if the opportunities for architectural training in Britain were ample, but judging from the action lately taken by the Architectural Association composed principally of the younger members of the profession, they do not consider the existing system of education entirely satisfactory, and during the last two years have promulgated a scheme, which is now in actual operation. The promoters this scheme, while disclaiming any intention of being nistic to existing institutions in which architecture is r of interfering in any way with the present pupilage ma k they can supply the particular education required air d o otherwise be obtained and better calculated to from floulents to pass the examinations prescribed by trades in t.

proposed curriculum of the Architectural Line valleys, it extends over a period of four years, foot. Joints to be to have 4 in. lap in

of Greek and Roman architecture, their origin, development and application; the several varieties of classic ornament; the nature of ordinary building materials and the elementary principles of construction; plane geometry applied to actual work; projection of solids and development of surfaces; elementary physics as applied to building; the rudiments of perspective mensuration, chemistry, geology, geometrical drawing of ancient examples and free hand drawing.

Second year—English architecture from the Conquest to A. D. 1500 and the successive development of the styles; the characteristic mouldings and ornaments of each period; the nature of ordinary building materials and the elementary principles of construction continued from the first year; the calculation of the strength of materials; land surveying and levelling; chemistry of building materials; elementary ornament and color decoration; drawings of ancient examples; free hand drawing; solid geometry.

Third year—History of architecture and features of mouldings and ornament; materials and their application in building; strength of materials; specification writing and taking of quantities; ornament and color decoration; sanitary science as applied to drainage; elementary natural philosophy, including light, sound, heat, hydrostatics and electricity; designing and construction of modern buildings; free hand drawing; perspective; construction masonry.

Fourth year—History of architecture; materials and their application in building; sanitary science, including water supply, ventilation, lighting and heating; measurement and valuation of buildings; professional practice; design and construction of modern buildings; drawings of ancient buildings; graphic statics and perspective; modelling and water color.

From this brief description of what is being done in Britain for architectural training, it is evident that it is a subject of vital interest to the profession, and one which at the present time is receiving greater attention than has ever before been given to it.

This interest in the education of architects is not confined to Britain. In France the subject has received the attention of the State, so that some two years ago an Official Commission in Paris was appointed to examine the legal conditions under which the profession of an architect is exercised, the system of study which gives access to it and the character of the diplomas granted in connection with this study. This Commission after a year's investigation, in which they were assisted by provincial societies of architecture, made a report respecting the training to be obtained in Provincial Ecoles des Beaux Arts, and called attention to what they considered defects in the system, the principal defect being that after providing a course of training to qualify as an architect no diploma was granted that would give the holder of it a status as an architect duly qualified to practice his profession. In the report the Commission also calls attention to the peculiar legal responsibility for his work which the law imposes upon an architect in France, and points to the anomaly that while the State exacts certificates of proficiency from contractors doing work of the most common character, it requires no certificate of proficiency or diploma from the architect who is supposed to be a compendium of knowledge in all that relates to building. The Commission recommend the establishment of district schools in affiliation with faculties of the State for the study of architecture, and that entrance to them should only be obtained after the candidate has shown by examination that he is sufficiently advanced in his studies to enable him to follow the special course of instruction necessary for his training as an architect.

The course of instruction recommended for these schools embraces pretty much the same subjects as are provided for in the curriculum of the Architectural Association to which I have already referred, and consists of the study of architectural forms, analysis of monuments, study of design, decorative art, history, archæology, perspective stereotomy, hygiene, theoretic, technical and practical construction, ventilating, heating, lighting and professional practice.

The Commission strongly recommend the granting of diplomas to those who pursue the full course of construction and pass the examinations, and to make the diplomas of value they suggest that only those holding diplomas shall be entrusted with government or municipal work.

The subject of architectural training has of late years received a large share of attention in the United States, where in addition to many art and technical schools of local character that afford assistance to architects' pupils in the prosecution of their studies, there are several universities, colleges and institutions which have Chairs of Architecture in which a full course of architectural training may be obtained. Among the institutions I may mention the Universities of Cornell, Illinois, Philadelphia, Columbia College and the Institute of Technology, Boston. In each the course of instruction extends over four years, and their curriculums embrace all the subjects of a scientific and art character necessary to qualify their graduates for practice. In the first two years other subjects are taught which do not pertain directly to architecture, but in the last two years of the course the studies are almost wholly confined to architectural subjects. The art schools of the Metropolitan Museum of Art in New York also conduct courses in architecture, which are so arranged as to prepare pupils who desire it for admission to the Ecoles des Beaux Arts in Paris, while for pupils who are engaged in architects' offices, and cannot devote the time necessary for a full course, special classes and lectures are arranged to occupy only

part of the day or evenings for special subjects, instruction in which could not be obtained in their offices.

From the brief description of what is being done for architectural training in Britain, France and the United States, it will, I think, be evident that it is a subject which at the present time is considered of great importance, and is receiving a large share of attention. From the experience gained during the last twenty years, the consensus of opinion appears to be that study in the scientific and art subjects before referred to are essential to fully equip an architect for fulfilling the duties of his profession.

While the subject of architectural training has of late years and in other lands received great attention, and facilities more or less complete have been provided for imparting instruction in the special subjects required by an architect, no attempt has yet been made in the Dominion for the foundation of a Chair of Architecture in connection with any of our universities or colleges, nor are there any schools of art or technology in which pupils who have already entered upon the study of architecture in offices can obtain any practical assistance in the prosecution of their studies. Some time ago there was a rumor that the Minister of Education for the Province of Ontario intended founding a Chair of Architecture in the University of Toronto, but the scheme has not yet materialized.

It is to be hoped, however, that the Associations of Architects now formed in Ontario and Quebec will in the interests of the architects agitate for some means of affording the special instruction required by present and future pupils in preparing them to pass the examinations required by the respective Associations, either by the foundation of Chairs of Architecture in connection with our existing universities or colleges, or by the establishment of lectures and classes in immediate connection with the Associations. It would be premature at this early stage in the history of the Associations to suggest any particular scheme of education, but I feel that the necessity for affording some means of instruction in special subjects to present and future student associates, to enable them to pass the final examinations for registration, will soon force itself upon the attention of the associations.

For the present it would be a step towards and preparation for a more complete scheme if the Faculties of Applied Science of one or more of our universities would add a Chair of Architecture, and by means of lectures or classes in special subjects, afford instruction in such subjects as cannot very well be obtained in the daily routine of an architect's office.

At the present time the faculties of law in connection, I believe, with McGill and Laval Universities, while providing for a full course of instruction qualifying their graduates to pass the examinations for admission to the bar, also provide for lectures at such hours as will admit of students in law offices attending them, and that attendance on these lectures are compulsory on the students. If some such arrangement as this could be carried out, it would meet the present requirements.

NOTE.—Since preparing this paper I am glad to learn that a Chair of Architecture has been founded in the University of Toronto, and that Mr. C. H. Wright has been appointed as Professor, and hope that other universities may soon follow the example set them by Toronto.

MR. P. W. ST. GEORGE, CITY SURVEYOR, MONTREAL.

CANADIAN CITY ENGINEERS.

I.

THE subject of the accompanying portrait, Mr. Percival Walter St. George, City Surveyor of Montreal, was born at Torres, Morayshire, Scotland, on the 22nd of October, 1849, being the youngest son of Lieut.-Col. James D. N. St. George. After having spent seven years in France and at the University of Edinburgh in acquiring an education, he came to Canada in the year 1866.

The first two years of residence in this country were spent on the Nova Scotia Railway, and the succeeding four years, from 1868 to 1872, on the construction of the Intercolonial Railway. During the year 1873 Mr. St. George was engaged on the North Shore Railroad; 1874 saw him back again on the Intercolonial road. The following year his services were given on behalf of the Northern Colonization Railway.

From 1875 to 1873, he held the position of Deputy City Surveyor of the city of Montreal. In the latter year he was appointed engineer-in-charge of maintenance way on the Norfolk and Western Railroad, of Virginia. In December of the same year, he received the appointment of City Surveyor of Montreal. He was a member, in 1886, of the Royal Flood Commission of Montreal; associated with him were Messrs. Thos. Keefer, John Kennedy and Henry Perley.

Mr. St. George is a member of the Institution of Civil Engineers, of London, of the Council of the Canadian Society of Civil Engineers, also of the Association of Municipal Engineers of Great Britain. He married in 1872 Flora Stuart, only daughter of the Rev. Canon Townshend, rector of Amherst, Nova Scotia, and has issue six children.

HALIFAX, N. S.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

TRADE DIFFICULTIES.

IN this city each trade has its own association, and nearly all city tradesmen are members of their respective associations. Then here is the Amalgamated Trades and Labor Union. When any member of an association has a greviance to complain of against his employer, or when an employer violates the rules of an association, the case is investigated by the association to which the aggrieved belongs, or whose rules have been violated, and if the investigating committee find that the employer has dealt unjustly with an employee, or contra to the rules of the association, or violated the rules of the association in any way, and refuses to comply or rectify wrongs, the matter is laid before the amalgamated union, and all members are under obligation to quit work on that employer's job until he has made amends, &c. One of the rules of the Painters' Association was that no master painter should have more than three apprentices in his employ. The firm of Thomas Reardon & Co. took on a fourth apprentice, insisted on retaining him, and set him to work on the City Club building, now in course of erection, which resulted in a strike of all workmen on that job. Reardon's entire staff of painters being union men, quit work on his other jobs. Other master painters endeavored to assist Reardon, which caused their union men to strike also. This strike on the City Club building occurred during the last week of August. About a fortnight after, master painter David Roche, who was one of the parties that tried to assist Reardon, and who had the sub-contract for painting the new Catholic Glebe House, now in course of erection, sent an apprentice to prime work on that job, when all hands there struck work. Then followed strikes on several other jobs from similar causes.

Manufacturers and master workmen of the various trades then formed an Association, when committees from this and the Amalgamated Trades and Labor Union met a number of times to try and arrange a settlement. Two difficulties stood in the way of a settlement. First, Reardon positively refused to adhere to the painters' rules regarding the number of apprentices to be employed, and the other master painters sided with him in this respect; secondly, a day or two after the strike on the City Club building, two union painters went back to work with Reardon, thereby making themselves liable to a fine of $5 per day according to the rules of the Painters' Association, and which the painters demanded before agreeing to a settlement with the master workmen's Association. The latter, however, considered it unfair to these men who stuck to their work during the strike to leave them unprotected by their Association. Finally, after many meetings, it was agreed to leave the case of these men to be dealt with by the Painters Association. As to the apprentice question, an agreement was reached by the Manufacturers and the Trades and Labor Council, which provides: That all strikers shall at once resume work, the number of the suspended members of the Painters' Union to be left with the Union to be dealt with; the pay of painters' apprentices to be $2.50 per week the first year, with an increase of $1.50 per week each year, including vacation, but excluding bonuses; every apprentice must be able to read and write the English language, and be not less than 16, nor above 21 years of age; every apprentice must agree to abide by the rules jointly agreed upon by the Associations; master painters must keep apprentices under legitimate instruction and otherwise comply with the conditions of agreement; a record to be kept of all apprentices employed, and the term of their apprenticeship; the joint committee of the two Associations to supervise the employment of apprentices, adjust all appeals preferred either by employers or apprentices, and for cause terminate apprenticeships, or place an apprentice with a new employer; apprentices to be entitled to and to be paid for one week's vacation; a certificate to be furnished the joint committee by the employer when an apprentice has completed his term, and the seal of both Associations shall be attached to such certificate, which shall then be accepted as evidence of the holder's right to rank as a journeyman. The agreement further provides that no strike is to be inaugurated until the points in dispute have been submitted to the Manufacturers' and Master Mechanics' Association and the Trades and Labor Council, and if necessary, referred by them to arbitration. If the latter course is adopted, the decision of the arbitrators is to be final. Should a member of either Association infringe in any way the conditions of this agreement, the Association to which he belongs shall forfeit the sum of $100. Unfortunately, strong opposition has developed in the Trades and Labor Council to the ratification of this agreement assented to by its representatives, while the union painters refuse to go to work until the question regarding the non-union men is settled, consequently a final adjustment of the entire difficulty, which was supposed to have been well-nigh reached, seems to be almost as far distant as ever.

Master Mechanics Association and the Trades and Labor Council, which

If lead and oil paints do not wear as well as of old, as so many claim, they have at least been partially replaced by the Cabot shingle creosote stains, which wear as well, are cheaper, and give a coloring effect far more agreeable and artistic than is obtainable by any of the old methods.

TORONTO ARCHITECTURAL SKETCH CLUB.

At the meeting held on Nov. 9th, Mr. John Millar, of the J. F. Pease Furnace Co., addressed the members on the subject of "Heating." The president of the Club, Mr. Pearson, occupied the chair.

Mr. Millar said: "I appear before you to night to give a talk upon the important subject of heating buildings. My experience has been gained in a practical way, and from this point of view I propose to talk to you this evening; it is possible that views may be advanced that will conflict with your ideas, but a great deal of knowledge is gained by hearing the opinions and experiences of different men engaged in every given line, and I will leave you to form your own conclusions.

"The three great systems of heating are by the use of steam, hot water and warm air." (The speaker here explained the meaning of the terms "direct," "indirect," and "direct-indirect" heating by steam and hot water, and went on to explain further heating by the system known as the "combination.") "This can be done by a combination of steam and warm air, and by hot water and warm air. The advantages of this system over steam and hot water are, that perfect ventilation can be secured at less expense, and perfectly free from any danger of the system freezing up. The pure air from the outside of the building is passed into the heater and out through the registers, warmed, giving forth sufficient pure warm air for ventilating. The balance of the heat required is given by the radiators which may be placed in rooms at a distance from the heater.

Of the different systems, heating by warm air is the cheapest, and in greater demand than any other, but there are many difficulties in the way to secure good results. These to a great extent can be removed by you, and I propose now to deal with some of them and point out to you how they can be obviated.

"It is of great importance that a good location be secured for the heater, and just here you can assist the heating man to advantage; arrange your cellar rooms so that the heater can be centrally located, if necessary giving the rooms to the north and west the advantage."

Here the speaker made a sketch of the ground floor of a building, showing how it could be heated with the very best results, and without taking up very much room in the cellar. In Fig. 1, dotted lines show the furnace and pipes in the cellar. Another sketch was made (Fig. 2) showing how some architects would like to have the work done.

"It would be of great advantage to the furnace men if larger space could be secured to run pipes to large and exposed rooms. This can be done by using 2 x 6 studding in place of the 2 x 4 which is generally used. A little forethought on this particular point will make a heating system a success that would otherwise be a complete failure."

"Ground floor registers should be placed in the floor. They may be placed in the wall provided there is capacity enough in the space between the studding for the size of pipe required, but

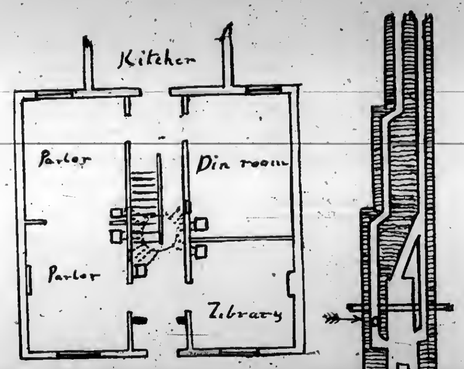


Fig 1

Fig 3

very much better work can be secured from registers placed in the floor."

The attention of the audience was then drawn to the defects to be found in chimneys. Fig. 3 shows a defective flue, when by making the change to the other side of the chimney (Fig. 4) a good flue can be had for the heater, leaving the crooked flue for the fire place. The flue should be straight without openings except that for the smoke pipe, and well and smoothly parged."

The speaker then spoke of the proper position in rooms for warm air registers and steam and hot water radiators.

"Registers should be placed as far away from windows as possible, and on the opposite side from a fire place. This cannot always be done, people do not build houses to suit the heating apparatus, so we have to do the best we can with the house presented for the work.

"Steam and hot water radiators should be placed near or under windows; they radiate heat and warm the air coming in contact with them. Warm air from the furnace is conducted, and if conducted into the room near a window, the warm air is cooled quickly by coming in contact with the cold surface of the glass, and falling to the floor cold, cannot be heated."

As there is no rule to guide in laying out a system of heating by warm air, the speaker's advice was that architects should not

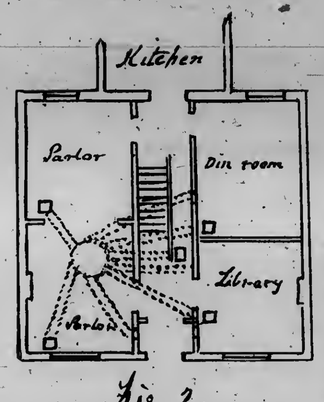

Fig 2

Fig 4

attempt the work, but leave it to the heating expert, especially as a guarantee is always given to heat the building.

In conclusion he thanked the Club for the close attention they had given him, and said he would be pleased to answer any questions, or explain any points that might not have been made as clear to them as he would have wished.

An interesting discussion took place, Messrs. Curry, Gregg, Johnson, and others taking part.

Mr. Curry explained some very interesting points, and referring to the lecturer, said "we have had one of the most instructive lectures given to us in a long time."

A hearty vote of thanks was passed to Mr. Millar, the chairman expressing the opinion that the speaker had fully covered the subject.

The following is a synopsis of the "Talk" on Classic Architecture" at the Club rooms, Oct. 26th, by Mr. Gambier-Bousfield, A.R.I.B.A. (Mr. Bousfield had prepared some rough crayon sketches of details of proto-classic caps and a map of the countries in which the art flourished before the birth of Christ, and these were exhibited together with prints from various professional journals bearing upon the subject.)

The lecturer called the attention of the chairman to the absence of note books among the students, and urged upon them the necessity of taking notes, as he also advocated very strongly that the students should come prepared to ask questions at the conclusion of the "talk," as discussion was the only way to bring out points that a lecturer might have omitted, especially in an extemporary "talk" like the present. He said he was gratified at being invited to give the opening "talk" of the season, and only regretted that more time had not been allowed him for the preparation of a paper, but he trusted that his audience would exercise patience towards a man unaccustomed to extemporary speaking. He did not intend to treat so much upon the subject of proportion as to show how false was the notion that the Greeks "*invented*" the orders, and to explain how the orders were developed from previous and distant empires. The Greeks were, as a nation, the most conceited people that ever lived; they attempted to show to their posterity that they invented everything they made use of—that they even invented astronomy—even if they did not go so far as to pretend they invented the stars. Certainly they were a wonderful people, possessed of a genius unknown before, but had it not been for the foundation of art laid in other countries hundreds of years before, upon which the Greeks added a superstructure, they could never have attained to such perfection in the art as they did.

To understand this, it would be necessary to take a glance at the map, which exhibited the boundaries of some eight or ten great empires that preceded the republics of Greece. There was the Egyptian empire, dating from B. C. 4,000 to B. C. 600; the newly discovered, but no less important, empire of the Hittites, covering the whole of Asia Minor and holding away alternately with Egypt over Syria, where history ran concurrently with that of Egypt, or from about 2,300 B. C. to 1,300 B. C. (The lecturer here called attention to the fact that he was purposely making use of round numbers in his dates to simplify the subject.) Then in the centre of that area which had at its four corners the Black

CANADIAN ARCHITECT AND BUILDER.

VOL. IV.—No. XII. TORONTO AND MONTREAL, CANADA, DECEMBER, 1891. PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),

PUBLISHED ON THE THIRD SATURDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

14 King Street West, - TORONTO, CANADA.

64 TEMPLE BUILDING, MONTREAL.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

CLOSE OF VOLUME IV.

THE present number completes the fourth volume of the CANADIAN ARCHITECT AND BUILDER. A comprehensive index to this volume is presented herewith. As a result of continued effort and the generous support which we have received, we are enabled to look back upon a year of progress. Satisfactory increase is shown in the number of subscribers and advertisers, in return for which, we have sought to add to the value of the paper. Nowhere do we find information of equal quantity and value supplied for so small a price. Our policy in the future, as in the past, will be to endeavor to increase the value of the monthly and weekly issues to the fullest degree warranted by the measure of support accorded us. To every reader we extend the wish for a Merry Christmas and Happy New Year, and to those who have assisted in any way to advance the interests of the CANADIAN ARCHITECT AND BUILDER, may 1892 bring added prosperity.

WE regret to learn that our esteemed contemporary, the *American Architect*, has recently suffered considerable loss and inconvenience in consequence of the building in which are its offices having been partially destroyed by fire.

The publication of Mr. Doran's paper on "Building Inspection," read at the last meeting of the architects and students of Montreal, together with several other articles intended to appear in this number, is unavoidably deferred owing to unexpected demands upon our space.

THE sketch which we present of Mr. Chas. Baillairgé, City Engineer, of Quebec, outlines the record of an unusually busy and useful life. Conjoined with a brilliant mind, Mr. Baillairgé is the possessor of a lightsome disposition, and the physical ability to work eighteen hours a day. To this fortunate circumstance is no doubt largely due the extent and value of his accomplishments, and the fact that at the age of sixty-five, a further period of usefulness appears yet to lie before him. That such may be the case, is the wish of his many friends.

THE near approach of the municipal elections is being taken advantage of by the Toronto Trades and Labor Council to urge upon the city Council the passing of a by-law for the inspection of scaffolds. A committee consisting of three members of the Trades and Labor Council, three members of the Builders' Association and the City Commissioner, has been appointed to draft a by-law and report. Such a by-law as the one proposed is not likely to prove satisfactory to anyone except those who may succeed in getting appointments as "inspectors." Builders will have the right to insist that when the by-law comes into operation their liability for accidents on ("inspected") scaffolds shall be transferred to the city.

THE Toronto plumbing by-law makes it compulsory that the drainage in all new buildings shall undergo proper inspection. The ordinance is a wise one, and is, we trust, faithfully administered. There is reason to regret that it was not enacted at a much earlier period in the city's history. The character of much of the work done prior to the existence of the present law, is of the worst description. The outbreak of disease has led in recent instances to an examination of some of these uninspected drains, disclosing the fact that they were laid in the most careless and criminal manner, without the use of an ounce of cement. It is safe to assert that many a life has been sacrificed to this wilful neglect, and as the provisions of the present law are not retroactive, the injury will continue.

A CENSUS was recently taken of the vacant houses in the city of Toronto. The number is shown to be about 4,000. By some this is taken to indicate lack of prosperity. Others do not so regard it. They point to the fact that many of the houses that are vacant are old and dilapidated, and have been deserted by their occupants for those of modern date wherein greater convenience and comfort are afforded. It should also be borne in mind that houses are constantly being erected which, having been ill-designed and planned, appear to everyone except the builder to be undesirable, and consequently are shunned by house-hunters. Making due allowance for such causes as mentioned, we are nevertheless of the opinion that four thousand vacant houses is a greater number than should exist. We believe it to be the fact that increase in population has as yet failed to overtake the abnormal building enterprise following what is known as the "Toronto real estate boom."

THE corner-stone of the county and city buildings at Toronto was laid by the Mayor in the presence of a distinguished company of citizens, on the 21st of November. Unfavorable weather marred to a considerable extent the proceedings. The occasion called forth reference to the progress made by the city of Toronto and the Dominion since a similar ceremony was performed in 1844 in connection with the erection of the present city hall. Seven years have elapsed since the first steps were taken to obtain a suitable site on which to erect the new buildings. A great deal of time was spent by the city and county authorities in arriving at a satisfactory understanding on all points. The work was further delayed pending the vote of extra money by the citizens. Subsequently there arose the dispute over the payment of a clerk of works, and this was followed again by the death of one of the contractors. The massive foundations are now in however, and it is hoped that nothing will interfere with the completion of the building in the shortest period consistent with thorough workmanship.

A SETTLEMENT of the differences between the carpenters and joiners and master builders of London, England, by reason of which building operations in that city have been paralyzed for six months past, has at last been reached. Mr. J. Macvicar Anderson, President of the Royal Institute of British Architects, who was asked to adjudicate upon the case, and by whose award both parties to the dispute consented to abide, has announced his decision. Some of the minor demands of the workmen, touching the hour at which work should begin, etc., are found to be sustained by the evidence. The demand for increased pay, however, is found not to be sustained, the conditions, such as the decrease in the trade of the country, pointing to the curtailment rather than the expansion of wages. The arbitrator calls attention to some results of this strike which we have not before observed, but which are worthy of the serious consideration of carpenters and joiners, as being in some degree likely to succeed a strike in any part of the world. On this point the arbitrator says: "The recent strike has been the means of inflicting injury on the trade of the carpenters and joiners of London, from which, in my judgment, it will not recover, for a large amount of carpenters' work has been superseded by other methods of construction which are likely to be increasingly adopted in future."

THE scheme for bringing water for Toronto use from Lake Simcoe will probably die the death of its aldermanic sponsors, and will be interred with their bones on the ides of January next. Apart from the fact that the quality of the water is much inferior to that at our doors—simply to be had for the pumping—the cost of the enterprise would considerably outweigh its possible advantages. It is stated that the revenue for power supplied to manufacturers would be enormous. We have shown in a previous issue that the idea is fallacious. If the power is to be distributed hydrostatically to the different factories, new mains of immense size would have to be laid all over the city—if electrically, the loss in transmission, cost of maintenance of apparatus, and the *smallness of the available power* would put revenue out of the question. Especially would this be the case were the whole arrangement under municipal control. Then it is stated it would do away with the necessity for a trunk sewer, probably by using the present suction pipe as an outlet. Even if it were large enough it must be remembered that it could only be reached by means of a trunk sewer intercepting all the others. The power to be developed by the city water supply from Lake Simcoe, which would have to be developed miles outside the city in any event, is purely a figment of the imagination, and it is well that the citizens should have this fact impressed upon them before they determine to spend fifteen or twenty million dollars to get bad water.

THE Canadian Society of Civil Engineers has issued its ballot list for officers for 1892. Mr. John Kennedy, chief engineer, Harbor Commissioners, Montreal, has been nominated for president, and an opposition ballot has been issued in favor of Mr. E. P. Hannaford, chief engineer of the Grand Trunk Railway. It appears from the regulations of the society that a Nominating Committee is specially struck at each annual meeting to prepare this ballot. This committee is elected by the whole society. In its composition it is made as representative as possible. The duty of the society is to acknowledge its wisdom in selecting this committee and accept the nomination made by them. The rules empower any five members to present a list of names to the council, who shall issue them for ballot. This gives an opportunity for certain distficts or branches, such as mining, electricity or hydraulics, to be represented, but after the decision of the Nominating Committee has been announced, an opposition ballot should be issued only for very special reasons, none of which appear to exist in the present case. We look upon the nomination of Mr. Hannaford as a compliment to him from some of his numerous personal friends; the wisdom of it is doubtful. He has been placed in opposition to the carefully considered selection of the specially appointed Nominating Committee, with whose duties and powers he is fully conversant. As a former vice-president and member of the council, Mr. Hannaford has rendered good service to the society. He has shown many tokens of his deep interest in its welfare. He has now an opportunity of serving it still more, and he can by a very simple act lay the society under a perpetual obligation, and create for himself an even greater and higher *prestige* than that which he so honorably occupies.

AT intervals during the last three years the necessity of providing means of imparting technical instruction to artisans has occupied the attention of the City Council of Toronto. On each occasion the question, after having been to some extent considered, was on various pretexts "referred back." So frequently did it meet this fate, that its friends were almost ready to despair. It is therefore doubly gratifying to the friends of the movement to observe that definite action has at last been taken. An appropriation of $6,000 for the purpose of founding a technical school has been voted in Council, and a Board of Management appointed, comprising representatives of the City Council, the Architectural Guild, the Trades and Labor Council, the Association of Stationary Engineers and the Manufacturing interest. The Toronto Architectural Guild will be represented on the board by Messrs. S. G. Curry and Mr. E. Burke. It has wisely been decided to establish at present but one school, to be located in the centre of the city. The course of instruction has not yet been outlined. The selection of subjects to be taught is a matter requiring the most careful consideration, and will, we trust, be approached with due deliberation and a proper knowledge of the requirements of the various classes of students. In view of the decadence of the apprenticeship system, it is from technical schools the coming generation must receive instruction of an elementary character pertaining to the various trades, a fact which should give additional interest to the present movement. Gratifying success has attended the classes for technical instruction conducted for several years past in the city of Montreal under the direction of the Council of Arts and Manufactures of the Province of Quebec, and if equal interest is manifested, the success of the Toronto school will be assured.

Messrs. J. M. Williams & Co., of Hamilton, Ont., have leased the stove foundry of Mr. Mowat, at Dundas, Ont., and are starting it up with a force of fifty hands, for the manufacture of stoves, furnaces, etc.

The Richmond Slate Manufacturing Co., have purchased a slate quarry in the county of Brome, near Sutton Junction, Que. It has been reported on as being very valuable, and so situated as to be capable of being very easily worked.

COMPETITION FOR CHURCH DESIGNS.

THE Presbyterian Church in Canada has determined upon making an effort to improve the architecture of its churches, and with that object proposes to issue a pamphlet containing approved designs with letterpress explaining the same and essays on church architecture.

It is proposed to have a competition of designs for churches as per the list of requirements given herein, and to illustrate those designs which may be deemed of sufficient merit by the experts. It is hoped that there will be such a hearty response on the part of the architects that the committee will be enabled to publish designs suitable to the needs of all congregations. It is to be distinctly understond, however, that only such designs will be illustrated as may be deemed by the experts to possess architectural merit worthy of illustration. In case there should not be a sufficient number of good designs sent in to permit of the publication of the pamphlet, the same will not be issued. The plan and perspective, with possibly one elevation, will be illustrated, as it is not desirable to give sufficient drawings to allow of the design being made use of except through the author. This pamphlet will be placed in the hands of representatives of every Presbyterian congregation in Canada, and it is hoped that any congregation proposing to build will select from amongst the designs the one which most nearly fills their requirements, and instruct the author to prepare drawings for the erection of the proposed church at the regular commission.

The publication of the pamphlet will at least bring before the notice of congregations proposing to build the names of architects who are competent to design churches of some architectural merit, which should benefit those who have been successful in having their designs illustrated.

The following prizes, namely, $75, $50, and $25, will be given to the three best designs in order of merit, irrespective of the class under which they have been sent in. No money prize will be given to any design which is not of sufficient merit to allow of its being published, even though the same should be the best submitted in the competition.

Any architect who would like to send in designs for illustration and who does not care to enter the competition for the prizes, may send in designs, and the same will be published provided they are of sufficient merit in the judgment of the experts.

The experts, three in number, who will decide as to the merits of the designs which may be entitled to the prizes and the designs which may be of sufficient merit to be published, will be selected by the Council of the Ontario Association of Architects. The decision of the experts will be final on all points.

The excellence of a design will consist in the closeness with which the conditions have been fulfilled, the quality of the designs and the inexpensiveness of erecting the building. No limit has been made as to the cost in any class, as it is desirable that the designer should not be hampered except in so far that he must bear in mind that a good design which is inexpensive is of greater value than an equally good or even better design which will cost more money to erect.

The three designs which may be awarded the prizes will be chosen from among those standing first and second in the different classes. The experts will be instructed to favour the designs for small and inexpensive buildings in preference to those for large and costly ones.

The following drawings will be required: General floor plan, two elevations and one perspective. Other drawings may be sent in at the option of the designer. The drawings are to be in black and white to a scale of 8 feet to the inch. The plans and elevations are to be in line only, with the windows blacked in or not as may be preferred by the designer. The perspective should be a thoroughly good drawing, and may be rendered as thought proper by the author (but not in colour). The perspective is to be set up from a plan drawn four feet to an inch. Bad or inferior drawings will not be illustrated, no matter how good the design may be, but an opportunity will be afforded the author to prepare, or have prepared, suitable drawings.

Each competitor is requested to send in a short description of his design, and to state clearly the material which he would use in its erection, together with a statement of its cost. The experts will have a right to correct the estimate of cost placed on any design as may appear to them just. The above statement is to be printed in the pamphlet along with the selected design, together with the name of the author and his business address.

The following is a list of the classes of building which are required to meet the wants of the average congregations in each of the classes in which it has been thought well to divide church buildings:

1st. Country church to seat from 150 to 200 persons, with one room to be used as vestry and library. Church to be heated by stoves.

2nd. Village church, capacity 250 to 300 persons, with one room to be used as vestry and library. Church to be heated with stoves.

3rd. Large village church, seating 350 to 400 persons, with vestry and library. To be furnace heated.

4th. Small town church, seating 350 to 400 persons, with vestry, library and school room.

5th. Large town church, with seating capacity of from 500 to 600, with vestry, library, school room and kitchen.

6th. City church, seating from 600 to 1,000, with vestry, library, school rooms and kitchen.

7th. Large city church, seating from 1,000 to 1,300, with vestry, library, school rooms and kitchen.

In the last four classes the designer will himself settle the method of heating and arrange for same.

Competitors will please send in their drawings before the first day of April, 1892, to Mr. W. A. Langton, Registrar of the Ontario Association of Architects, Merchants' Bank Building, Toronto.

"CANADIAN ARCHITECT AND BUILDER" COMPETITION.

THE report of the expert appointed to judge the designs submitted in this competition is as follows:

OTTAWA, 18th Nov., 1891.

SIR,—I duly received the thirteen sets of plans which had been submitted in response to your invitation to students for competitive designs for a suburban cottage to be occupied by a young doing man business daily in the city, owning the lot, possessing $2,000 in cash and having an income of $1,500 per annum. This condition hardly seems to give a definite idea as to the outlay to be incurred, and does not appear to have been understood by many of the competitors. After examination of the various designs the following have been selected:

"Piapot" is given first place. The arrangement of the rooms in this plan are very good, but the entrance and vestibule are too small. The elevation is simple in design and well drawn. Altogether, both in plan and design, it appears to be the most appropriate for a suburban cottage. No perspective sketch.

"Kata Phusip" is given the second place. The staircases in this design are not so well arranged as those of "Piapot." The design is simple and appropriate, and the perspective is freely sketched.

"Jack Plane" is given the third place. The arrangement of this plan hardly entitles it to this place. The relative position of the dining-room and kitchen is objectionable, and there is no provision for servants stairs. The elevation is plain, and the perspective well drawn.

"Kata Phusin" is given first place for his perspective.

There is not much evidence of skill in the other designs, and they differ so little in degree that it is not worth while to attempt to grade them.

It occurred to me that in such a competition amongst "students," some consideration should have been given to the length of time the students have served in an architect's office, and also that a certificate should have accompanied each design, that all the drawings had been made by the competitor without outside assistance. There having been no condition to this effect, and as I had no information on the subject, only the relative merits of the designs have been taken into consideration.

The thirteen sets of plans have been returned to you this day by Dominion Express Co. I remain, sir,

Your obedient servant,

THOS. FULLER.

The names of the successful competitors are:—"Piapot," Mr. A. E. Wells, office of Mr. S. H. Townsend, Toronto; "Kata Phusin," Mr. W. Lawrence Munro, office of Mr. G. M. Miller, Toronto; "Jack Plane," Mr. J. W. Siddall, office of Messrs. Knox & Elliott, Toronto.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

Real estate for building purposes is reported to be in increasing demand in the upper western portion of the city.

The course of instruction in freehand, mechanical and architectural drawing, stair building, building construction, plumbing, wood carving, etc., under the direction of the Council of Arts and Manufactures of the Province of Quebec, is now open.

It is a pleasure to be able to state that the members of the Province of Quebec Association of Architects in Montreal have entered in earnest upon their work. Regular monthly meetings have been established, at which papers of interest to the profession are read and discussed. Since the publication of your last number, classes for the instruction of students have been formed. A large class under the direction of Mr. Hutchison meets every Thursday afternoon from five to six o'clock for the study of Roman architecture. Mr. A. F. Dunlop and Mr. Maxwell will conduct a pen and ink drawing class, and arrangements are now in progress for the organization of a modelling class.

At the regular meeting of architects and students held on Thursday evening last, there was a large attendance of students. Mr. Doran read a paper on "Building Inspection," which has been forwarded to the CANADIAN ARCHITECT AND BUILDER for publication. In his introductory remarks he stated that a committee had been appointed to deal with this subject, and pending the report of that committee, he would not refer to the present system of inspection, but would point out what he considered to be the requirements of a proper building inspection by-law. The discussion on the paper was taken part in by Messrs. Walbank, Hodson and Hutchison. A hearty vote of thanks was tendered to Mr. Doran for his valuable paper.

Mr. Andrew T. Taylor, the well known architect, of this city, was married on the 5th inst. at Holy Trinity Church, London, Eng., to Mary, second daughter of Assistant Army General J. Elliott, H. M. Ordinance Department. The best wishes of numerous friends will greet Mr. Taylor and his bride on their arrival home.

Mr. A. F. Dunlop left for Toronto and New York on Thursday last.

I regret to learn that the condition of health to which Mr. Clift, Secretary of the Province of Quebec Association of Architects, has been reduced by his recent illness, has made it necessary that he should indulge in a period of complete rest. Acting on the advice of his physician, he will leave shortly for Florida. It is earnestly hoped that the change may prove beneficial.

HOW TO ESTIMATE.*

By Wm. H. Hodgson, Architect.

II.

CARPENTER AND JOINER WORK.

	$	c.
7,000 ft. of hemlock timber (board measure) in joists, rafters, plates, lintels, etc., and labor in same		
21¼ squares (100 ft.) of ⅞ in. G & T flooring, 3½ in. wide, ground and 2nd floor		
12¾ squares of 1 in. matched flooring, 5 in. wide, attic and part cellar		
23 squares of ⅞ in. matched roof boarding, 7 in. wide		
21¼ squares of 1 in. rough boards, laid diagonally and carpet felt (between flooring)		
5 squares of 4 in. x 4 in. studding at gables, sheeting both sides, and on one side double thickness of sheeting paper		
33¼ squares of 4 in. x 3 in. stud partition		
25 squares of 2 in. x 1¼ in. furring, on walls		
1 square of floor pugging at gables, projections		
¼ square (75 ft.) of 2 in. planking on 4 in. x 4 in. cedars		
130 running ft. of 3 in. x 4 in. cedar joists bedded in concrete		
25 squares of beam and corbels dressed and moulded		
34 running ft. of denril, mould, cornice, etc., firm and secure		
98 running ft. of dressed headed facia, soffits and bed moulds to eaves		
60 rupning ft. of gable eaves, and bed moulds		
76 running ft. of narrow double beaded soffits, matched stuff and sheathing paper, tight to walls		
34 running ft. of matched beaded boards, and 25 dressed rafters		
69 running ft. of ⅞ in. matched sheeting 4 in. wide, 3 ft. high, and mould capping, grounds, etc.		
30 running ft. of ⅞ in. matched sheeting, 2½ in. wide, 5 ft. high, double beaded, capping grounds, etc.		
183 running ft. of 10 in. single base, with grounds scribed to floors and with fillets		
274 running ft. of 9 in. single base, with grounds scribed to floors, and with fillets		
220 running ft. of 7 in. torus base		
170 running ft. of angle bead		
92 running ft. of 3 in. ridge rolls		
100 running ft. of shelving and supports		
50 running ft. of 2½ in. picture mould—dining room		
30 running ft. of bead rail, and 40 hooks		
100 running ft. of 2 in. x 2½ in. dressed, slatted walk, on 4 in. x 3 in. cedars, and 24 ft. round curb, at front		
18 running ft. picket fence, 6 ft. high, to match gate		
2 hardwood sills to fuel doors, 3 x 15 x 16, weathered		
4 hearth's, boxing and trimming for same		
3 rows of 2 in. x 2½ in. herring bone bridging, 162 feet in all		
38 2 in. basement stair steps—stairs to attic and from porch to cellar		
15 1¼ in. stair steps, mould nosoing, and 1 landing, cherry rails, newels, brackets, etc., 2 in. turned pine balusters, etc., complete, and mould stand rail to closet b heath		
7 front steps, turned newels, and balustrade complete		
2 rear steps to porch		
1 2⅜ in. front outside door, oak veneer, complete with architraves, etc.; lock, $3.00, upper panel for glass		
1 2⅛ in. vestibule door in 2 pirts, mortice lock $2.50, complete as above, and brass bolts, and upper panels for glass		
2 2 in. porch doors, mortice $1.30 to ofie, and $2.00 to side brass bolts, fanlights, complete, as above		
13 1¾ in. ground and second story doors, mortice lock $1.35, brass bolts complete as above		
3 1¾ in. swing doors, complete as above, brass bolts and one doorway for jambs, etc., prepared to receive door		
4 1¾ in. 3rd story doors, complete as above, morticed $1.. 2 of them with fanlights		
1 2¼ in. sliding door, over head tracks, patent hangers, sliding door lock and flush handles complete, as above		
4 1⅛ in. head and flush doors, complete frames, etc., rim locks		
2 fuel doors, panelled, etc., complete, hung on top		
1 side dormer window		
7 (windows) for mould casings outside		
1 borrowed light, etc., complete		
5 cellar windows, complete, hung on top		
1 2 in. large front sash, mould transom, elliptic fitnlight for plate glass complete, architraves, etc., and with Willer slide blinds, in pocket behind window back		
21 2 in. English sashes, 3 of them for plate glass, and 3 with transoms, fanlights and Willer sliding blinds, as above		
5 semi-circular head sashes, complete		
30 centres for 30 arches		
3 chimney saddles		
2 cold air inlet and stout wire guard, hinged valve, etc., firm and secure		
1 bath fitting up complete, cherry sheeting and cistern, 30 in. x 18 in. x 14 in.		
2 water closets complete and 1 wash basin; cherry ends and seats, double lid for slop sink		
2 sinks fitting up complete, and hardwood capping		
2 dressers in kitchen and pantry, doors, drawers, shelving, etc., complete		
6 tiers of 1 in. shelving supports to kitchen and pantry		
2 tiers of 1⅛ in. shelving, each end of larder		
1 hanging shelf in larder and iron rods from ceiling		
6 shelves in linen closet, ends enclosed with cedar joists and spring catches		
1 side gate, rounded posts, footed and capped and hardware complete		
2 fuel bins—1 large for furnace coal and smaller in kitchen		
Fit up 4 bed room closets with rails and 24 hat and coat hooks; and shelves, etc., complete		
Bracketting for 3 plaster arches, and cove in drawing room		
Dressing ends of 76 projecting rafters to main roof		
Trimming registers and cutting for hot air pipes, etc., attendance on plumber cutting holes, boxing pipes, etc., etc.		

NOTE.—Beginning with bearing timbers, (undressed) the measure, thus: joist 30 ft. x 10 in. x 3 in. = equal to 6 ft. 3 in. cube—to bring into board measure; multiply by 12 (for a foot square) gives the board measure 75 feet. Flooring, roof boarding, studding, furring, &c., measured length and breadth, thus: 25 ft. x 16 ft. gives=400 ft., equal to 4 squares of 10 ft. x 10 ft. Lineal measure or running feet applies to cornices and dressed work generally, the sizes stated either in quantities or specification. Items in numbers, such as doors, windows, &c., as above.

SLATER.

	$	c.
24½ squares (100 ft.) of Rockland slating on 1 ply tarred felt		
5 squares of Dancy's Ontario tiles on 1 ply tarred felt		
32 lineal feet of galvanized iron valley linings, 15 in. to 18 in. wide		
98 lineal feet of galvanized iron strips, 5 in. wide at eaves to gutter		
12 lineal feet of galvanized iron strips 15 in. wide on cornice (3 front windows), 6 in. up behind tiling		
92 lineal feet of galvanized iron strips, 28 ounce, ridges		
Step and cloak flush to (5) chimneys and walls, cheeks and apron of dormer		

NOTE.—Measured, and contents given in squares, before mentioned, lineal measure, also, and the sizes as above.

TINSMITH.

	$	c.
98 lineal feet of galvanized iron, 28 gauge, eaves troughs 5 in. wide and holdfasts		
34 lineal ft. of 4 in. galvanized iron, 28 guage, to porch		
75 lineal ft. of 4 in. octagon down pipes to porch, 3 connections to gutter and drain pipes		
16 lineal ft. of 3 in. octagon down pipes to porch		

NOTE.—The measurements for this work as given above, lineal.

PLUMBING AND GASFITTING.

	$	c.
95 lineal ft. 1¼ in. iron gas piping, hold fast, &c., leaded joints		
118 " 1 " " " " " "		
90 " ¾ " " " " " "		
147 " ½ " " " " " "		
32 " ¼ " " to fire places, with cocks and keys		
30 lineal feet of ½ in. iron gas piping to gas stove in kitchen		
90 " " ⅝ in. lead supply water main pipe, 8 lbs. to the yard		
100 lineal feet of ½ in. lead supply pipe, branches, 6 lbs. to the yd.		
105 " " ⅝ " " hot water, 8 lbs. to the yard		
22 lineal ft. of ½ in. lead waste and overflow pipe, plated rim to bath		
10 lineal ft. of ½ in. lead pipe (heavy) and Dubois trap and screw		
28 lineal ft. of ¾ in. lead waste, 3 lbs. lead safes and brass flap valves		
37 lineal ft. of 4 in. cast iron soil pipe, tarred, and holes, screws, &c., complete		
4 lineal ft. of cast iron soil pipe, 6 in., above roof and flashing		
110 lineal ft. of 4 in. cast iron soil pipe at basement, digging, levelling, &c.		
12 lineal ft. of 2 in. cast iron soil pipe waste, with iron hangers		
35 lineal ft. of 3 in. cast iron vent pipe, with vent connections		
10 lineal feet of 4 in. cast iron pipe with return bend top		
20 lineal feet of 3 in. galvanized iron vent pipe		
12 lineal ft. tin speaking tube, silver plated mouth piece		
1 14 oz. copper bath, Dubois trap, plated plug and chain complete		
1 marble earthenware oval wash basin, counter sunk, marble top, back and end; Mott's, standing waste, Dubois trap and screw brass clamps		
1 porcelain flushing rim washout water closet (Inodore or Unitas) valve, balls and ball cocks, &c., complete, cistern lined with 4½ lbs. lead, &c., with porcelain drip tray, complete		
1 flushing rim water closet in basement, trap, cistern, etc.		
2 plated double Fuller bath and basin cocks		
1 key cock and hose connections		
1 soap and waste cock, boxed in		
1 7 in. dia. enamelled valve at bath room, ceiling		
1 9 in. x 12 in. dia. enamelled valve at kitchen, ceiling		
1 1¼ in. counter sunk marble safe, under water closet, &c., complete		
1 pair brass Fuller cocks		
1 galvanized iron cylinder, 40 gals. and stand, ¼ brass connections, shut off cocks, inch iron pipe to stove, ½ supply cock and ¼ sediment, pipe and cock		
2 cast iron sinks, trapped, &c., complete		
4 vents to waste pipes, and Y branches, 1½ and 2 in.		
2 vents to waste pipes and to water closet, 3 in.		
1 30 in. galvanized iron sink, brackets and enamelled backs, &c., complete		

NOTE.—In these works there are many and various items, as will be noted in the above, comprising lineal measure and numbers.

PLASTERING.

	$	c.
1041 1-9 superficial yards of 2 coat work, hard white finish		
404 2-9 superficial yards of 1 coat work on walls		
233⅔ superficial yards of 2 coat work, lime washing		
11 1-9 superficial yards of 1½ in. thick mortar, attic floors		
70 lineal feet of cove, drawing room, ceilings and walls		
66 lineal ft. of 24 in. cornice, dining room		
73 lineal ft. of 20 in. cornice, halls		
24 lineal ft. of 15 in. cornice, vestibule		
26 lineal ft. of mould beams		
2 30 in. centre pieces		
1 18 in. centre piece		
30 window and door frames for filling, air tight		

NOTE.—Superficial measure is given, that is, the walls and ceilings are measured through, openings are measured and deducted from same, showing the net number of superficial yards done. Cornices and other moulds in plaster are lineal measure, the girths of same added for mitreing internal and external angles. Centres are numbered, giving diameters.

PAINTER AND GLAZIER.

	$	c.
440 superficial yards of 3 coats painting		
287 superficial yards of staining, oiling, and 2 coats copal varnish		
34 superficial yards of oiling, and 2 coats copal varnish		
216 superficial ft. double diamond star glass		
33 superficial ft. diamond star glass		
15 superficial ft. ground glass		
40 superficial ft. stained glass, glazing only		
15 superficial ft. rolled cathedral glass		
7 superficial ft. rough rolled plate		
1 pane plate glass, 5 ft. 4 in. x 3 ft. 8 in.		
3 panes plate glass, 3 ft. 4 in. x 2 ft. 7 in.		
1 pane bevelled glass, 2 ft. 3 in. x 2 ft. 3 in.		
4 pairs blinds, &c., 3 cts. and priming		
Cleaning windows, and scrub floors twice, &c., complete		

NOTE.—Painting measured and given, superficial yards in quantities as shown. Glazing, measure superficial feet, and in plate glass at per pane, with size stated.

*The first of this series of articles, together with the plans and specification on which the bills of quantities are based, appeared in the CANADIAN ARCHITECT AND BUILDER for November, 1891. Back numbers will be supplied.

CLIMATIC INFLUENCES UPON ARCHITECTURE.

By G. F. Stalker.

The elements with which an architect is bound to concern himself in the preparation of his designs, and in the course of his practice, are so varied and so numerous that it is almost impossible to catalogue them. It is a still more difficult matter to assign to each its proper position of importance; for what would exercise a dominating influence in one country, and under a certain line of circumstances, would be of little account in another country and under changed conditions.

This may be said to be a kind of truism and so apparent as to render it almost unnecessary to be set down here. Still the fact remains, that buildings have been, and are being erected, by architects of good ability, which are disappointing and unsatisfactory. Artistically, and on paper, the designs may be most creditable to their authors; but practically, and *in situ*, they are failures. The cause of this may be the fact that this truism, like all other truisms, and just because it is a truism, is very much overlooked or neglected. And there is probably no element affecting architectural design so frequently and so easily left out of consideration as that of climate. One would think that this cannot certainly apply to Canada, for everyone knows that here we have plenty of climate. But when we are engaged upon our designs we are generally comfortably officed, and we become so engrossed in working out the architectural lineaments of some pet style or theme, that we forget that just outside the window the thermometer registers zero, the snow is deep in the streets, and the wind is keen.

The artistic treatment and scientific construction of a building are the chief characteristics which distinguish an architect from a builder. But common sense does not belong exclusively to any class of men, neither is it the outcome of any kind of technical education; and architects, like other men of professional culture, are sometimes distinguished for their want of it. And so it happens that artistic skill is often misapplied, and constructive ability absolutely wasted for very lack of common sense. We admire the beautiful conceptions of men of genius, and are sometimes tempted to imitate them, without giving a thought to the suitableness of local surroundings and circumstances. Fashion is an absolutely despotic mistress over all who swear allegiance to her. And there is such a thing as fashion in art. And just as we see the votaries of fashion in dress attired in Canada in a style which is only suitable for Paris or London, so we find the followers of fashion in art designing their buildings as if locality and climate were in these days reduced, by some artificial means, to a universal dead level. But nature will assert herself in spite of us, and if we wilfully and persistently blind ourselves to the fact that dress was originally, and is still, primarily intended as a covering for our nakedness, and a protection against the scorching sun of summer and the biting frost of winter, and that buildings were, and are still, primarily erected as shelters for man, we must expect to pay dearly for our temerity in so doing.

The problem, in this respect, set before architects in Canada is, it must be confessed, more difficult in solution than in countries where the difference of the temperature in summer is not evidenced by such a tremendous dip of the mercury in winter as we are accustomed to. We do not make our own weather, but the climate of this country, like that of all other countries, is practically a settled thing, and, in a general way at least, pretty well understood. It cannot be said to be capricious, neither is it uncertain, and, on the whole, it is not very variable; one year resembles very closely those that have gone before it. But we can say this of it, that it is very decided. We have a very short spring and a very short autumn; but when summer is here, we might as well be living in the tropics, and when winter is with us we are practically absolutely ice-bound. Business men, engaged in whatever industry of our country you like to name, are forced to take our climate into their reckoning. They would be considered almost culpably careless and negligent of their duty if they did not. Even building operations must be suspended during the winter; and this, of itself, should be a sufficient reminder to architects that our climate is a very important and potent factor in true Canadian architecture.

It may be urged in this connection that we can accomplish all that is necessary to bring the natural elements into subjection by artificial means. We can defy the frosts of winter by our furnaces, stoves and winter sashes, and we can modify, to a bearable extent, the heat of summer by a judicious adjustment of summer blinds. And for such mercies, even coming "in such questionable shape," let us be thankful. But it is not wise to rest and be thankful with such a condition of things. The effects of climate have had a very direct influence upon the minds of all the great architects of the world; so much so, that wherever a true style of architecture has grown into existence, we can, from the buildings which still remain as examples of it, almost infallibly tell what were the climatic conditions of the country and the time to which they belong. A thorough student of architecture is as little likely to go astray on this point, after a careful examination of a building, as he would be in regard to the date of its erection. And when we consider how carefully and systematically buildings were designed and erected in ancient times (for nothing was done in a hurry then) this is not to be wondered at. What was more natural than that the architects in those days, being allowed time to think, and to think of everything, should give some consideration to the climate of their country in the preparation of their designs? And to what other cause can we ascribe, for example, the difference in the forms, and particularly the slopes of the roofs, that have always been, and are still considered characteristic features of the several styles of atchitecture? There is nothing in the internal arrangements and formation of an Egyptian building that of necessity demands that it should be covered with a flat roof, neither is it necessary from structural or æsthetical reasons that a Gothic building should be finished externally with a pitched roof. But Egypt is a country of almost perpetual summer, and its climate is dry, while western and north-western Europe are damp and rainy.

If one reflects for a little on some of the more striking points which distinguish one style from another, and endeavors to find a reason for such marked and distinctive features as exist, one is forced to admit that climate has had a very powerful influence in the production of such a variety of architectural expression. True, it has not been the Alpha and the Omega of design, but it has existed from the beginning and will continue to the end, asserting its prerogative and refusing to be left out of consideration in any style of architecture that pretends to be true and national. The size and number and the positions of openings, the aspect of buildings, the sites on which they were erected and the general disposition of their parts, were not matters which were allowed to arrange themselves at hap-hazard, nor be chosen or decided upon carelessly. They were the outcome of the imagination, the result of foresight engendered by long experience, and the thoughtful and vigorous application of keen intellectual acumen, regulated to a very large extent by a wholesome utilitarianism and a recognition of surrounding natural exigencies. But if we continue our reflections a little further, and call to mind the general features of the buildings which have been erected in recent years, and in Canada in particular, we cannot fail to be struck with the want of consideration that has been shown to Dame Climate. We certainly have not a Canadian style of architecture, though considering our age as a nation this is a pardonable offence, if offence it be. But we have not even given a Canadian expression to any style that we have followed. Norman Shaw, in England, revived Queen Anne, but he clothed his work with such freshness and originality of treatment, that one can scarcely recognize in his buildings that they are only a revival of a defunct style. And so with Richardson, of Boston. He revived and modernized the style of Normandy and the north of France, but he treated it in such a manner, and made it so suitable to the local surroundings he had to deal with, that his work only bears a family likeness to its original. So also with Thomson, of Glasgow, who designed in as pure Greek as if he lived in the days of Phidias, but who had mental vigor enough to make the style of his adoption his servant, and to look as much at home among the rugged hills of cloudy Scotland as in the plains of sunny Greece; and these men, being men of genius, have each had their crowd of imitators who have, in their turn shown us how much and how little they have imbibed the spirit which animated their great masters. Norman Shaw revived in England a style that had been practised there more than two hundred years ago, and had been found suitable to the country. Richardson revived, in the northern states of America, a style which existed nearly a thousand years ago in a country subject to climatic conditions similar to his own, while Thomson's revival was only in the spirit of pure Greek architecture, the local and climatic conditions of Scotland being entirely dissimilar from those of Greece. In each case, however, the revivals were successful, and depended for their success not only on the great artistic ability and natural genius of these men, but on the manner in which they grasped and gave expression to local surroundings and modern requirements. And it is in this latter quality that the greatest distinction between Shaw, Richardson and Thomson, and their host of disciples lies.

It has already been said that there is such a thing as fashion in art; and it may be safely affirmed that the three most fashionable styles of architecture at the present time are Queen Anne, Norman and Neo-Grec, and Norman Shaw, Richardson and Thomson are respectively the prophets of these schools. Some might be disposed to call them the modern leaders of fashion in architecture, but this would be derogatory to their great names, for they are in no way responsible for the "run" which their distinctive revivals have had. On the contrary, being men who could appreciate true art in any style, they would have preferred to see men of great ability striking out in roads of their own finding, where they would have had more freedom and probably have discovered and set before the world new beauties, rather than follow in their wake (sometimes too

blindly) and produce designs which can only be said to be "after" their manner.

Now, let it not be understood for a moment that these observations are made in the spirit of fault-finding. It is quite natural, and the thing to be most expected, that men of genius in any walk in life will have followers. But the thing which is not always done, which, in fact, is rarely done (more's the pity), is to follow them intelligently. Had any of the three men, to whom reference has been made, lived and practiced their profession in Canada, the probability is that they would have brought about the same revivals which they have done, but their respective styles would have been made to serve the local and climatic conditions of this country, whereas those who have followed Shaw and Richardson into the Queen Anne and Norman styles (the Neo-Grec has not taken root here) have erected buildings which would have suited England or a more southern climate very well, but which are altogether unsuitable for Canada.

But the fact of the great difference in the climate of this country from that of any of the countries where a national style of architecture has exised, or does exist, so far from casting a damper upon our architects, should stimulate them to accomplish what has hitherto been neglected, and to give a Canadian cast of features to our buildings. The Greeks took as the basis of their noble marble structures which are still among the glories of art, the humble wooden huts of the primitive days of the country. But these huts had all the requirements of good buildings, as far as they went, and they were admirably suited to all their local surroundings. There are huts in Canada too, which those who have lived in them tell us afford stronger protection against the severity of our winters at all events than our modern houses. And, if we want examples of greater refinement in buildings than there is to be found in our log shanties, but which have fulfilled the requirements and stood the test of a climate similar to our own, we can find them in the picturesque Swiss chalets, or in the more substantial villas of the northern Tyrol. But it would be, perhaps, as unwise to imitate these as to continue in the line of imitation that has taken such root among us. The chief thing, the only thing for us to do in this matter, is not to ignore our climate, although it can treat us with supreme contempt, but to give it in our architecture that consideration and study which is its due, and which will give a certain amount, at least, of national character to our buildings.

ONTARIO ASSOCIATION OF ARCHITECTS.

THE Council of the Association met on Wednesday, Dec. 16th. Present, Messrs. Storm, Rastrick, Edwards, D. B. Dick, Arnold, Burke, Curry and Townsend.

Of the business done the following is of general interest:

The Registrar was instructed to open a register for assistants desiring employment. Any registered draughtsman out of employment may send in his name to the Registrar without fee, and the Registrar will send lists of all names so received to any registered architect applying for it.

In the matter of the Presbyterian Church Competition, it was announced that the Committee Board of the Presbyterian Church having the matter in hand is about to issue a circular to architects containing the conditions of a new competition.

A form of Students' Indenture has been adopted by the Council for the use of members of Association, and when printed may be obtained free of charge on application to the Registrar.

Examiners were appointed for the examinations to be held on April 7th.

Preparations were made for the proceedings of the next convention.

ESTIMATING.

17 BERRI ST., MONTREAL, Nov. 26th, 1891.

Editor CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—The remarks in the last issue of your valuable paper re Bills of Quantities seem very opportune. Nothing at times causes so much trouble and unpleasant feeling to all parties concerned as the disputes that will and do arise in reference to the quantities contained in a structure. The English system of employing qualified quantity surveyors works most satisfactorily, and I can speak from experience, having had seven years in that branch of the profession, also estimating. They are prepared much in the same way as is described in that concise and lucid series of articles now running in your journal on "How to Estimate," by Mr. W. H. Hodgson. I may think of any use to you, I will gladly send you a copy, say, a legal and printed form of contract is also in use amongst the building fraternity which alike protects employer, architect, and contractor, and is of the most detailed character. If you together with blank bills of quantities of a large contract for your perusal or publication if you think of any material use.

Yours very truly,

WM. STANLEY GOSNELL.

P. S.—If you would not take it out of place, I would ask, could you not open a column in your widely read paper for "Situations Vacant and Wanted, &c." for the convenience of the building trades generally.

OUR ILLUSTRATIONS.

"CANADIAN ARCHITECT AND BUILDER" COMPETITION FOR A SUBURBAN COTTAGE—DESIGN BY "PIAPOT" (MR. A. E. WELLS, TORONTO), AWARDED FIRST POSITION.

A note accompanying this design says:—"The author has sought to obtain the most favorable aspect for the various rooms, and at the same time keep them in their proper relation one to another. The parlour and library both have a south aspect, and the dining room is placed where the rays of the morning sun will flood the room at the breakfasting hour. The library and verandah adjacent, overlook the lawn. The entrance is placed where it does not interfere with the privacy of the verandah or lawn, and being on the east side of the house, it is sheltered from the cold winds of winter.

The kitchen at the north-west corner of the house, projects sufficiently to the west to admit of a south window; thus it is not dependent for sunshine on the low rays of the western sun, which in summer would make the room uncomfortably hot. The sill of this window is placed sufficiently high to prevent the verandah and lawn being overlooked from it. The second window in the kitchen is placed diagonally opposite this one, in order to ensure thorough ventilation by a current of air across the kitchen.

The kitchen is separated from the dining room by a passage that has direct communication with the outside air, with the doors so placed that the interior of the kitchen cannot be seen from the dining room.

The kitchen and sewing pantry, by not being connected by a door, both gain in accommodation. The stairs to the cellar is arranged so that the person tending the furnace need not pass through the house to get at it.

The soil pipe stack runs straight up through sewing pantry and bath room, and the fixtures in each floor are grouped around it, so that the cost is reduced to a minimum and the whole system is very simple and direct. It will be seen that every fixture has an abundance of sunlight about it.

The bath room is placed with regard to the convenience of the occupants of the different bed rooms. None of the bed rooms on this floor have sloping sides, but are finished under the rafters with a plaster cone about two feet in radius.

The cost of this house would probably range from three to four thousand dollars, which amount could be raised easily on the security mentioned in the conditions of competition.

PHOTOGRAVURE PLATE—RESIDENCE ON MADISON AVENUE, TORONTO, E. J. LENNOX, ARCHITECT, TORONTO.

"CANADIAN ARCHITECT AND BUILDER" COMPETITION FOR A SUBURBAN HOUSE—DESIGN SUBMITTED BY "KATA PHUSIN" (W. LAWRENCE MONRO), AWARDED SECOND POSITION.

RESIDENCE FOR MR. JAS. HEDLEY, ST. JOSEPH ST., TORONTO. S. H. TOWNSEND, ARCHITECT, TORONTO.

"CANADIAN ARCHITECT AND BUILDER" COMPETITION FOR A FRONT FENCE—DESIGN BY "ARM AND HAMMER" (A. EWART, OTTAWA).

TORONTO ARCHITECTURAL SKETCH CLUB.

THE regular fortnightly meeting was held on the 7th inst. Mr. Pearson, president of the Club, being absent from the city, Mr. Barrett, vice-president, occupied the chair.

Different subjects of interest bearing on architecture were discussed, Messrs. Gregg, Parker, Wells and Woolnough taking part.

Messrs. H. Boswell, T. Connell and W. Mollington were elected members of the Club.

CORRECTION.

TORONTO, Dec. 10th, 1891.

Editor CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—In your next issue kindly correct a printer's error in the report of my remarks on Classic Architecture before the Toronto Architectural Sketch Club, which is misleading, though the context may set the reader right. It occurs on page ix. of the November issue, first column, third paragraph, fourth line, "that of the Syrians" should read "that of the Lydians." There are a few other typographical errors, but probably the reader would know them to be such. For instance, "Medinet Habon" and "Bern Hassau" should be Medinet Habou and Beni Hassan.

Yours truly,

R. W. GAMBIER-BOUSFIELD.

It is a relief, says Mr. Brown, in *Painting and Decorating*, after the endless succession of houses finished in hard wood white pine stained in many cases—to find a return in the better work to china gloss. Many people imagine that this class of work looks well only in white, but I have seen some very nice effects in colors, especially in pale and delicate tones. One room in pink was very dainty, and another in blue gave a very pretty effect. A parlor finished in chocolate and gold was rich and warm in color tone, and the gold gave a much more brilliant effect than when used with the customary accompaniment of white. The gas fixtures in this room were in gold ormolu, thus harmonizing with the woodwork.

CANADIAN CITY ENGINEERS.

II.

MR. CHAS. BAILLAIRGE, C.E., M.A. & F.R.S.C., City Engineer, Quebec, since October, 1866, was born at Quebec, Sept. 27, 1826, and is therefore now 65 years of age. His father, P. F. Baillairgé, who died in 1865 at the age of 68, and who had been "Road Surveyor," Quebec, for 36 years and up to the time of his death, was a son of F. Florent Baillairgé and of Melle. Cureux de St. Germain, both of French origin. His mother, Charlotte Jauverin, daughter of Lieut. Horsley of Her Majesty's Navy, was born in the Isle of Wight, England, of Helen Welling of Jamaica, Long Island, N. Y., whom he met and married there after the War of Independence of the U. S. Our subject's grand uncle, Frs. Baillairgé, de "l'Academie Royale de Peinture et de Sculpture," France, and who carved several of the statues of the Basilica, Quebec, had his studio in the quaint old building, in St. Lewis street, opposite Parlor street, now occupied by Campbell's livery stables, and was almost daily visited during the latter's stay in Quebec by the late Prince Edward, Duke of Kent, father of our reigning sovereign, Queen Victoria.

Mr. Baillairgé, whose portrait we reproduce, was educated at the Quebec Seminary, where, finding the ten years curriculum too long and slow, he, after seven years tuition, entered upon the study of mathematics, philosophy, logic, etc., and commenced his apprenticeship in architecture, engineering and surveying, receiving his diploma as sworn surveyor of lands in 1847. At the age of 17 he, with another schoolmate, designed and built a double cylindered carriage for common roads, often at that time driving to the country with it, with his friends. In 1848 he married Delle. E. Duval, daughter of John, and step daughter of H. J. Duval, for many years Chief Justice of the Court of Appeals of Lower Canada, by whom he has had eleven children, four of whom survive.

During the nineteen years previous to his entering on his present occupation of city engineer in 1866, he designed and superintended the construction of the Laval University buildings, the asylums and churches of the Sisters of Charity and Good Shepherd, the Music Hall, the new jail, and of very many private residences. He designed and built the Church of Ste. Marie, Beauce, a view of the elegant interior of which, of Gothic architecture, appeared in Vol. III, No. 7 of this journal for 1890. Many other parish churches, presbyteries, school houses, cottages, villas and other structures were erected after his designs. In 1860 he erected on the St. Foy Road, the cast iron bronzed monument to the braves who fell there under General Levis in 1760, and to which Prince Gerome Napoleon contributed, at a cost of over $5,000, the crowning statue of Bellona.

R. CHAS. BAILLAIRGE, C. E. ENGINEER, QUEBEC.

Mr. Baillairgé was for many years hydrographical surveyor and engineer to the Quebec Harbor Commission, member and chairman of the Board of Examiners of Land Surveyors, and a representative of St. Louis Ward in the Quebec City Council from 1858 to 1861. His services have often been required by the Local and Federal governments, by the courts and clergy, and by private concerns, as arbitrator on disputed claims and boundaries, and on questions of technology, and during all this busy period of 19 years, laboring as he always has done and still does for 18 hours out of every 24, he found time to write and deliver in the old House of Assembly, Quebec, and elsewhere, numerous lectures and conferences on "Steam and the Steam Engine," "Pneumatics," "Mechanics," "Optics," "Astronomy," and the like. In 1863-5 he was called to Ottawa as joint Architect and Engineer with Messrs. Fuller and Page on the Parliamentary and Departmental Buildings, then under construction; and during those two years he completed in the French language, his 900 pages treatise (including mathematical tables) on "Plane and Spherical Geometry and Trigonometry," published in 1866, where he shows at page 330 the fallacy of Thorpe's pretended solution of the trisection of an angle, for which the Government Patent Bureau granted him letters patent of invention, poor man, after his laboring at the solution, so he says himself, during 34 years of his existence. Mr. Baillairgé's work, at pages 232 to 331, contains the solution of some 200 pertinent problems, among which he introduces at page 251 Mr. Steckel's elegant solution of the hydrographical problem of the four points, not heretofore solved by a simple geometrical construction. We would also invite attention to Mr. Baillairgé's easy solution, founded on his new theorem Prop. LX, page 189, of the heretofore difficult problem of dividing up land by a straight line running through a given point (page 197) and at page 280 to his novel solution of the important and difficult problem of laying out city lots between non parallel commercial streets where every inch of frontage is precious, in a way to contain given or proportional areas, with proportional frontages on each of the streets.

Since our subject has entered on his civic duties in Quebec, he has planned and built Dufferin Terrace, which is 1500 feet in length and flanks the crest of the cliff overhanging Champlain street at a height of 182 feet above mean tide level of the river St. Lawrence. The foundation stone of this structure was laid by Lord Dufferin in 1878, and the terrace when completed inaugurated and thrown open to the public by Their Excellencies the Marquis of Lorne and the Princess Louise in 1879. In 1881 he reported on, and in 1883-5 put in the new line of 30 inch water pipe from Lorette to Quebec, a distance of nearly nine miles. During his 25 years as City Engineer he has had occasion to plan and build wharves, ferry landing piers, slips, pontoons, and ferry boats. The new dredge and water works in the adjoining parish of St. Foy were planned and carried out under his superintendence, as well as those in the recently annexed municipality of St. Sauveur, under the more immediate direction of Mr. Gallagher, Asst. City and Water Works Engineer.

He has planned and built fire and police stations, market halls, etc., and many of his yearly reports, as those of 1868, '70, '72 and '78, are voluminous, interesting and instructive, and have been sought after by City Engineers and others of many portions of Canada and the United States. Steep hills have been replaced by grades of easy access; the fortification walls have been cut through and streets prolonged to meet those in the suburban districts; ornamental iron stairways have been erected as designed by him to afford communication between the upper and lower wards of the fortress city.

In 1874 Mr. Baillairgé published in both languages his "Key to the Stereometrical Tableau," "Clé du Tableau Stéréométrique," giving applications thereof to numerous solid forms. This system (see De Brodker's letter from the Ministry of Public Instruction, St. Petersburg, 14-20 February, 1877) was to be taught in all the elementary schools of Russia, and by a subsequent letter of a year and a half later, from the same source, Mr. Baillairgé was informed that "the system having been found to work well, will moreover be applied to all the polytechnic schools of the Russian empire."

In February, 1874, Mr. Baillairgé was called to France, when in the "Grand Conservatoire des Arts et Metiers" he received the gold medal of the "Societé de Vulgarisation de l'Ensignement en France," also the medal called "Philippe de Girard" given by M. de la Boronne de Pages' for the most useful invention or discovery of the year, and he has since received 13 medals of honor and 17 diplomas from France, Italy, Russia, England, Brazil, Japan, Belgium, Canada and the United States of America.

After the death of his first wife in 1878, Mr. Baillairgé in 1879 married, Anna, daughter of Capt. Benj. Wilson, of the English navy, by whom he had six children, four of whom survive.

In 1854 Mr. Baillairgé published in both languages "The Stereometricon," ("Le Stéréométrican") thus perfecting his system, by applying the prismoidal formula to some 200 elementary geometrical forms, giving in each case the nomenclature of the solid and of the class to which it belongs, the nature and mode of arriving at the areas of the opposite bases and middle or other sections, the form or shape and area of the developed lateral and other surfaces thereof, the object of which the model is representative or suggestive, and of the many other uses to which the figures may be applied. In 1880 our subject was chosen by Lord Lorne, then Governor General of Canada, as one of the members of the so-called "Royal Academy of Arts," and in 1882 he was made one of the foundation members of Section III of the Royal Society of Canada, before which he has read many papers, several of which have been published in the yearly transactions.

Being, as he is, of a humorous and versatile turn of mind, Mr. Baillairgé in 1873 wrote a play which he called "Le Diable devenu Cuisinier," which was played by the Mangard Company then in Quebec at the Music Hall, and then at Jacques Cartier Hall, to the great delight of the audience on each occasion, and in 1875, as member of the "Club des 21" of the literati, artists and savants of Quebec, he read a paper in which in his happy style, he hit off the peculiarities and portrayed the qualities of every member of the club, and of the chairman himself, the Count de Premio Real, then Spanish consul at Quebec. His later works are, in 1888, a French dictionary (some 700 pages) of homonymous words and of the component elements thereof; his last work of 1890 being a vocabulary of nearly 200 pages of "English Homonymes" and one of over 200 pages of "Homonymes Francais," both for the use of schools and educational purposes in general, and at different times he has edited articles on the art of building, the defects in our system of construction, and many other subjects too numerous to enumerate.

We may say in conclusion, that Mr. Baillairgé is of opinion that a good City Engineer should know enough of land surveying to plan and lay out streets and squares and take the levels absolute and relative thereof, widen and prolong them as required, and prepare "designs and "proces verbals" of all lands and parcels of land of whatever form or size, to be expropriated for the purpose; to lay out parks and banal grounds; that he should be enough of an engineer to grade and pave hills and roadways, lay down sidewalks, crossings, water channels and put in catch basins; to compute the size of plan and lay out and superintend the construction of city drains and sewers and water and gas distribution pipes, man holes, hydrants, drinking fountains, water troughs, etc.; to lay out lights, gas, arc or incandescent, and telegraph, telephone, fire alarm and light circuits, and attend to the position of each post (if for overhead systems), or put in underground channels therefor (if to be laid beneath the surface); to plan, specify and superintend the construction of retaining walls and crib work for roadways on side hills, wharves, ferry piers and landings, pontoons and slips and ferry boats, terraces, hills either straight or tortuous or zig-zag to overcome differences of level, public stairways of wood or iron and the like; to lay out city tramways, etc., etc.—and enough of an architect to plan and build fire and police stations, market halls, nests of shambles, weigh houses, public conveniences, elevators, crematories and the like.

PUBLICATIONS.

The *Canadian Shoe and Leather Journal* has issued an exceedingly attractive special number in the interests of spring trade, 1892.

The publishers of the *Dominion Illustrated* have issued a Christmas number which for beauty and interest is not surpassed by any European publication of similar character. The number reflects credit on the country as well as on the publishers. The announcement is made that the *Dominion Illustrated* will in future be published monthly as a magazine, the subscription price being reduced to $1.50

SOCIETIES.

The third annual dinner in connection with the School of Practical Science, Toronto, took place at the Arlington hotel recently. The faculty, graduates, guests and students numbered one hundred. The occasion was greatly enjoyed.

The General Water Pipe Co., of Liege, Belgium, is seeking information regarding the extent of the Canadian market, with a view to establishing a branch of its business here.

The importations of cement into Canada during the last few months is said to have been in excess of the requirements and dullness in the market is looked for in consequence.

SANITATION AND HEATING

STEAM HEATING.

AT this season of the year the heating of houses is a subject of interest to nearly every one. Many of the readers of our paper are especially interested in steam heating, and are now engaged in getting such appliances ready for the winter's work.

The most important part of a steam heating apparatus is the boiler, and next to that in importance is the furnace. Unless these are suitable and of sufficient capacity, all the rest of the apparatus will be found unsatisfactory, no matter how skilfully it may be done. Some steam fitters advocate the use of sectional boilers of cast iron, and containing the furnace within the parts of the boiler. These, no doubt, are cheaper and more convenient to sell and erect in place; but when that much has been said in their favour, the list of their good qualities is about complete. In some circumstances it is necessary to have a boiler in which steam is quickly raised, but it should be remembered that a boiler in which steam can be quickly raised is also one in which it will quickly go down, should the fire become dull.

For this climate, with its great variations of temperature during the winter, the boiler of a steam heating apparatus should be made large enough to give ample steam for the coldest weather, and the furnace part should be so arranged that the fire may burn slowly and yet maintain a steam pressure. The boiler should contain a considerable quantity of water, and it will be found of advantage to have the furnace of brick, so as to form a reservoir of heat, which will be radiated to the boiler whenever the fire becomes dull.

The boiler and furnace should be of such capacity and so arranged as not to require the constant attendance of the man in charge. The first cost may be more, but the annual expenditure for fuel, attendance and repairs will be less when the boiler is large and the furnace made so that a slow burning fire keeps up steam. The comfort and satisfaction obtained will more than repay for the greater outlay.

In another article the size of boiler and furnace in proportion to the amount of piping to be kept hot will be discussed—at present it is proposed to say something about getting ready for ater.

The boiler, it is assumed, is all right and not requiring any repairs; what, then, should be done in order to get ready? The boiler should be carefully gone over, and all dirt and dust removed from it and from the furnace. This should be done, even though it was all cleaned out in the early summer. The next thing to do is to remake the hand hole and man hole joints. The hand hole joints should be very carefully made, as they should be absolutely tight in order to prevent the slightest amount of leakage. Corrosion of the boiler head soon follows a little leakage at the hand holes. In making these joints, it is a good plan to use moderately thick rubber, and to make a paste of black lead and oil, and put it on both sides of the rubber. The hand hole cap should not be screwed up too tightly when the boiler is cold, and should be screwed up after steam has been up or the water at the boiling point. All the valves about the boiler and its connections should be examined, and the spindles properly packed if new packing is needed. Then close the blow-off cocks, see that any check valves either in the feed or return pipes are in order, and while free to rise have not too much lift. The lift should never exceed one-fourth the diameter of the valve, and may be less. Open the valves on the steam and return pipes, and then turn on the water and fill the boiler to within a couple of inches of the level at which it is intended to keep the water when steam is up.

While the water is being run in, the guage cocks, or safety valve, should be open to allow the air to escape from the boiler. The fire should then be lighted, and the water slowly heated until steam is raised. When steam has begun to flow through the pipes the valves at all the radiators should be opened, and any requiring packing marked for attention by re packing. If any radiators do not heat, the air valves should be opened to allow the air to escape.

When steam is up the return pipe should soon become warm, showing that circulation is going on throughout the apparatus. If it does not become warm, the cause of the stoppage of circulation should be searched out and removed.

ELECTRIC LIGHT AND HEAT.

IT is certain that we are upon the eve of great discoveries in the field of electrical science. The perfection to which electric lighting has attained, great as it is, is but the threshold as it were of the possibilities yet to be realized. When it is considered that of the amount of energy expended not one-tenth appears as light, leaving the larger proportion to take the form of heat, it is at once seen that absolute perfection is yet a long way off. Light without heat is the dream of the scientific explorer in the realm of nature, and when it is successfully achieved our present wasteful methods will appear crude indeed. We are burning up our stoves as well as our fuel. We are like the Chinaman who invented cooked pig—we burn down our house to get roast pork. The experiments of Tesla with currents of high frequency are upon this line, and may yet take practical shape. If a medium of sufficient tenuity could be found capable of transmitting the almost inconceivably rapid vibrations of light as set in motion and maintained by the subtle force of electricity, the grosser form of caloric would be passed and left behind, and the cold and brilliant aurora glow of heatless light would be attained. But where is this medium to be found? The molecules of ordinary metals are incapable of being attuned to the rapidity required. Copper, our best conductor, would probably be too inert to transmit the vibratory force, and be dead as so much wood. Although the electric current may be weighed and measured with precision and appears to follow certain fixed laws, but little is known of its actual constitution, and in what manner it is transmitted along the most favorable path. But there are immense possibilities in it, and before long we may look for further discoveries in its application to the production of light.

A valuable paper on "Sanitary Plumbing" was read by Mr. Cesare Marani, lecturer in Sanitary Engineering, at a recent meeting of the Engineering Society of the School of Practical Science. Messrs. Burke, Curry, Townsend and Bousfield, members of the Ontario Association of Architects, were present, and took part in the discussion which followed.

It is proposed in future to charge builders in Toronto with the cost of plumbing inspection in buildings under construction. The proposal is a proper one. There is no valid reason why the cost of this work should be charged against the general expenditure of the city. If inspection of old plumbing is required, a fee of $5 must be deposited by the person who desires the work done. There is no better reason for free inspection of new work than of old. The charge should simply form another item in the builder's estimate, and should ultimately come out of the pocket of the owner of the building.

A jury recently found the city of Toronto guilty of negligence in allowing foul-smelling refuse to be dumped in proximity to a citizen's dwelling, thereby causing an outbreak of diptheria in his family and the death of two of his children. While the verdict was undoubtedly just, the amount of damages awarded to the plaintiff—less than $400—was ridiculously small. It is well, however, that the courts should sound the warning that those who carelessly endanger the public health will be called to account. The comments of the judge upon the danger arising from the system of ventilating sewers into the public streets were timely. An improvement which would secure the discharge of sewer gas at such a height that it would not assault the passerby or invade citizens in their homes or places of business is urgently required.

PERSONAL.

The death has taken place since our last issue, of Mr. John T. Stokes, engineer of the County of York. Mr. Stokes held this position for twenty-five or thirty years. His life was one of great activity and usefulness, and the integrity and kindliness of his character caused him to be deservedly esteemed.

The friends of Mr. Ernest Wilby, formerly a member of the Toronto Architectural Sketch Club, who went to England early in the year with the object of prosecuting the study of his profession, will be pleased to learn that since March he has been employed in the office of Mr. Calcutt, a prominent London architect.

CANADIAN ARCHITECT AND BUILDER.

VOL. V.—No. 1. TORONTO AND MONTREAL, CANADA, JANUARY, 1892. PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),

PUBLISHED ON THE THIRD SATURDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

14 King Street West, - TORONTO, CANADA.

64 TEMPLE BUILDING, MONTREAL.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1891.

PRESIDENT	W. G. STORM, R.C.A., Toronto.
1ST VICE-PRESIDENT	KING ARNOLDI, Ottawa.
2ND VICE-PRESIDENT	F. J. RASTRICK, Hamilton.
TREASURER	D. B. DICK, Toronto.

M. PERRAULT	Montreal.
A. F. DUNLOP, R.C.A.	Montreal.
ALPH. RAZA	Montreal.
J. F. PEACHY	Quebec.

A FULL report of the proceedings of the second annual convention of the Ontario Association of Architects will be published in our next issue.

A GENTLEMAN from Toronto was a candidate at the recent examination for qualification as Associate of the Royal Institute of British Architects, and, we regret to observe, was not successful in passing.

A PUBLIC library to cost a million dollars or more is to be erected in Chicago. It is said to be the intention to ask for competitive designs, and to give $1,000 each to the authors of the five best designs. If these are the conditions, the inducements are too small to attract the efforts of men whose knowledge of the requirements of such a building could be relied upon.

THE fire losses in the United States during the year which has just closed, amounted to $125,000,000, being nearly 50 per cent. in excess of the previous year. This, despite the fact that there were no great conflagrations. The *Engineering News* points out that the expenditure of the money which thus goes up in smoke would go far towards rendering the buildings more nearly fire proof.

IT was the intention to publish in this paper drawings and specification in connection with the second of Mr. Hodson's series of articles on "How to Estimate." Some alterations in the drawings were thought necessary, however, in order that they might prove more instructive. This has made it necessary to defer their publication to the February issue. In this connection, if contractors see any way in which these articles might be made more serviceable, we shall be pleased if they will forward us their views on the subject. Any suggestion which may thus come to us will be carefully considered.

THE journeymen plasterers of Philadelphia refuse to work on the same building with graduates of the Plastering Department of the Master Builders' Trade School, of that city. The lads are desirous of completing their trade, and the master plasterers are anxious and willing to employ them. In pleasing contrast to the attitude thus assumed by the Philadelphia plasterers stands that of the Bricklayers' Union of Boston, which has arrived at the following understanding with the Master Builders' Association regarding trade schools: "Trade schools are to be established and opened evenings. Instruction therein is to be given all regularly indentured apprentices. None but regular apprentices shall be allowed to enter these schools. Instruction shall be given to pupils in the theory and science of the trade they propose to learn."

The Mansur-Tebbets warehouse in St Louis, constructed on the slow burning principle, was almost entirely destroyed by fire recently. The result is said to have been due to lack of promptness on the part of the fire department and scarcity of water, rather than to defective construction. Although the contents of the building were of a combustible nature, the fire burned for a considerable time on the two lower floors before extending to the upper stories. Mr. Edward Atkinson, the advocate of slow burning construction, referring to the destruction of this building, says: "I do not think that we shall reach the true fire-proof construction until we attain a method by which the building is constructed wholly of fire-clay, or brick and tile, without any wooden or iron members in the structure: similar to the method in which the new Boston Public Library

was constructed. I think that building comes nearer to being fire-proof than any building that I know; but such construction is, as yet, too expensive in this country to be applied to mills and commercial warehouses. It has, however, been adopted in Spain for textile manufactories, bleacheries and print works."

WHEN a metal beam or bar is subjected to a shock, there is a tendency to change the form or to bend the beam. When the load is removed or the shock is over, the beam will assume its original position unless the strain produced by the load or shock has been in excess of what is sometimes termed the elastic limit. It may be repeated an infinite number of times and yet there will be no evidence of any weakening of material, but if it be in excess of the elastic limit, it has only to be repeated a sufficient number of times to break the beam. However, there is another feature of the action of the metal which must not be overlooked. It is that the limit of elasticity is not constant throughout the succession of shocks required to break the beam. After the load has been several times applied and removed, it is found that a greater weight is required to produce the same amount of bending, that is, the limit of elasticity has been increased. It is, however, a question whether or not the safety of the beam has been increased.

A REVOLUTION is taking place in the methods of preparing stone for the various purposes which it is required to serve in building construction. In Chicago a great deal of the work formerly done by the skillful hands of the workman is now being accomplished in much less time and consequently at greatly reduced cost by improved machinery recently designed for the purpose. A gentleman who witnessed its operation states that the *modus operandi* is very similar to that to which lumber is subjected in passing through a planing mill—the material in its rough state entering at one end of the establishment and passing out at the other end in almost finished condition. Stone-cutters viewed the introduction of these machines with alarm, but the experience of the last two years is said to have shown that there is as great demand for skilled workmen as ever. The reduction in cost effected by the use of machinery has brought stone into use to a greater extent than before. There is likewise noticeable a tendency to indulge in more elaborate ornamentation. The employment of machinery would no doubt have lessened very materially the time and expense on the construction of the new Parliament, city and university buildings, Toronto.

THE difficulties incident to the erection of the Toronto Board of Trade's new building are not yet at an end. The limit set for the cost of the site and building was $350,000. The calculations regarding interest to be paid and probable revenue to be derived from tenants indicated that it would be possible to put aside annually the sum of $5,000 to establish a sinking fund for the redemption of the bonds on the building. There is little reason to doubt that had the construction of the building been entrusted to local architects, it would have cost little if anything more than the sum fixed as the limit. The secretary and Mr. H. W. Darling, a former president of the Board, were apparently very desirous that an American architect should be employed, and the upshot of the matter was that the work was given to Messrs. James & James, of New York. After a time rumors began to circulate that there were serious flaws in construction due to defects in the plans. The secretary of the Board positively denied that there was anything wrong, but eventually when this journal with the aid of sketches and figures taken from the work, printed the true facts of the case, it could no longer be concealed that blunders of a serious character had been made The architects were dismissed, and another American architect employed to complete the work, as it would never have done to have admitted that a mistake had been made in passing by competent local men. The mistake is none the less apparent in the fact, however, that the building required to a large extent to be reconstructed, and in consequence the limit of cost has been exceeded by $120,000. This extra cost has wiped out the possibility of devoting $5,000 a year to a sinking fund without increasing the fees of the members. As the only way out of the difficulty, it is now proposed to amend the by-laws to permit of doubling the amount of the annual membership fee. As a result of this proposal we have recently heard members asking one another what advantage was derived from their connection with the Board, and the answer was that the benefits to members other than those belonging to the grain section, are nil. Under these circumstances it is not surprising to hear members offering to sell out. "You will never be able to pay off the debt on that building in the world!" was the statement made by a member to one of the trustees of the Board the other day in the writer's hearing. "I know it," was the discouraging reply, and this was followed by the suggestion that it was useless to expect of economy as long as the Board had a secretary whose economic ideas were so ill-defined.

O. A. A. CONVENTION.

THE second annual convention of the Ontario Association of Architects will meet on Tuesday, the 2nd of February, at the School of Practical Science, Queen's Park, Toronto, at 2:30 o'clock, p.m. It is to be hoped that the proceedings will be of more interest than usual. We would strongly urge on every member of the Association to be present and take an active part in the proceedings.

Members who do not attend the annual meetings cannot justly make any complaint as to the manner in which the interests of the Association are conducted. If any member feels that some question which specially interests him should be considered, he should attend and bring the matter up, otherwise there may be no one present to bring it before the meeting.

This is a critical period in the existence of the Association, and it will require the assistance of every member to tide it over the next few years. If the members are loyal to the Association its success is assured. But if the members grow indifferent and careless, it will require all the energy and perseverence of its active workers to carry the Association until it has made for itself a solid foundation on the ability and loyalty of its younger members who will have come in by passing the examinations.

There are members who complain that the Association has not benefited them because they cannot obtain 5 per cent. commission, other members being prepared to work for less. The Association is unable to make rules or regulations which will bind the members except to a very limited extent, and certainly it is unable to force its members to charge any definite commission, even if such a course were advisable. When a man does not value his services at the regular rate of commission, but at a rate much lower, nothing can be done that will cause him to value his services at a higher rate. His services may not in reality be worth more than he is willing to receive, or he may be forced by circumstances to take what he can get.

It is a question if it would not be better for each man to settle for himself what his services are worth. A fixed rate of commission on all work of the same character to be paid alike to the competent or incompetent architect is unfair and unjust alike to the architect and the client. The client, if he knows what is best for him, will go to the most competent man that he can find, as he would not pay any more for his services than he would for those of an inferior man, except that a competent man will insist upon the work being thoroughly done, thus increasing the cost to the proprietor. This and similar questions could be brought up and discussed at the convention with benefit to all.

The testing machinery which has been recently erected in the School of Practical Science will be exhibited, and tests will be made of the building stones in use in the province of Ontario. Five well known members of the Association have consented to exhibit plans of houses and describe them, giving their reasons for arranging the plans as shown. These descriptions and the discussion which will follow will probably be of great interest.

There will be a number of valuable papers read, which, with the discussions upon them, should be of interest to every member. It is hoped that some members will come prepared to discuss the papers. Every member may not have the opportunity nor be able to take an active part in the work of the Association, but each member is able and should take sufficient interest in the progress of the Association to cause him to do all that may lie in his power, be it much or little, to assist and encourage those who are taking an active part. The member who does nothing to aid in the advancement of the Asssociation

but who is prepared to find fault and object to everything that is done, is not worthy of being called an architect.

The object of the Association is to advance the interests of architecture by educating its members to a knowledge of the work which as architects they are called upon to perform. By architects studying each other's work and exchanging ideas, the profession will attain to a higher standard of general proficiency which will raise its members from among the careless, ignorant, or for-gain-only architects of the present day.

The architect who follows his profession simply as a means of livelihood will see no benefit in any Association if it does not increase his income. Personal gain is his only object, and to obtain it he is prepared to erect any manner or description of building, from the most dangerous to life to the most inartistic conception that man can be guilty of designing.

The object of the Association is not to determine a tariff of fees and insist on its members maintaining them, but to work earnestly to raise the members to a higher standard of architectural knowledge, so that they may be enabled to demand and obtain just and reasonable remuneration through the fact that their services are absolutely necessary to the successful erection of every important building, if it is to serve the purpose for which it is being erected.

There are some who think that the architect who has a large practice is more interested in the success of the Association than the average member. This is far from true, for the man with a good practice is independent of any Association, and the more inferior in ability his opponents remain the better it is for him. It is the average man and the young architect who will benefit through the success of the Association and the general advancement of the profession.

Do not let any man think that he is unable to assist in the work of the convention. Every one can do something, and out of love to his profession let each member do all that lies in his power.

PRESBYTERIAN CHURCH COMPETITION.

WE write to draw the attention of our readers to this competition. The Presbyterian Church recognizes that the architecture of its churches is not creditable, and desires to bring about an improvement. The method decided upon is to issue a pamphlet with short essays upon architecture, to instruct the congregations as to what is good church architecture. To do this, thoroughly good designs are absolutely necessary for illustration, and such can only be obtained from architects.

The church can not afford to pay for designs for publication in the pamphlet in the usual way, so it was decided to ask the assistance of the architects. This assistance is now asked, and it is hoped a hearty response will be made by the architectural profession. The profession is interested in this movement, and should give it reasonable assistance and support.

There are many architects who are not any too busy at present, who should be able to send in good and suitable designs. Some may say that they will not do so because they will not receive any recompense. Well, such is a fact, but have they not in very many instances to the injury of the profession persisted in preparing designs and forcing them upon prospective clients when they were not asked to do so in the hope of being able to obtain a commission? Now in this instance, the preparing of a design may lead to a commission, possibly to many commissions, and there is nothing small nor lowering in the transaction, but the opposite, as the Presbyterian Church will be assisted in their effort to improve the church architecture of this country, and the competitor will have the pleasure of feeling that he did what he could.

There are many young men, and for that matter draughtsmen in offices, who could enter this competition with advantage to themselves and very probably with advantage to the object of the competition. Young men should seize this opportunity to find out just how they stand in comparison with their confrerés.

We strongly urge upon all architects and draughtsmen to render every assistance that may lie in their power to make this effort on the part of the Presbyterian Church a success.

A GOOD CEMENT.—For a glass-metal cement insoluble in carbon bi-sulphide, alcohol, water, etc., dissolve gelatine in water, add a small percentage of glycerine, and also a small quantity of potassic bichromate.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

THE hardware manufacturers and dealers of this city have started the circulation of a petition to the Government asking that a uniform appraisement of articles charged duty under the same clauses of the tariff at various ports of entry throughout the Dominion be arranged. The complaint is made that much inconsistency is shown by appraisers, and that in consequence of imperfect knowledge on the part of appraisers, imports at small ports enter at lower rates than in the cities.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

The semi-annual examination for admission to study and for registration of the Province of Quebec Association of Architects, will be held at the Parliament Buildings, Quebec, on Monday, 25th January, at 10 a. m. Intending candidates are required to give one month's notice to the secretary, Mr. Chris. Clift, accompanied by the necessary fees: For admission to study, $10; for registration, $25.

A meeting of the Council of the Association was held on the 7th inst., the president, Mr. Berlinquet, presiding. It was decided to have a printed list of the names of all registered architects sent to members, that reasonable time should be allowed members to pay their fees, and should any fail to pay arrears within the specified time, their names will be struck from the roll.

In compliance with a request received from the Ontario Association of Architects, a Committee was appointed to arrange for the reading of a paper by a member of the Quebec Association at the approaching annual Convention of the Ontario Association.

It was agreed that all monies paid into the Association by students should be used directly for their benefit.

The Committee on tariff legislation reported that on account of the unsettled state of political affairs in the province at present, action by the Government had been delayed, but the indications are that if the tariff is not fixed too high, it will receive the sanction of the legislature.

Messrs. Dunlop and Maxwell have now a class of twenty-one students. It is the intention when the students are sufficiently advanced to take them out on sketching tours.

A paper was to have been read by Mr. Hayes, but the author found himself unable to prepare it before the next meeting.

BOARD OF TRADE BUILDING.

The sum of $200,000 has been subscribed towards the erection of the Board of Trade building. This is less than half the amount required, and judging by the difficulty experienced in obtaining it, considerable effort will be required to secure the balance. In a wealthy commercial centre like Montreal, money should be freely forthcoming for an enterprise of this kind. The methods of the Building Committee resembling so closely those of the Toronto Board of Trade, it may be that like results are expected to follow, which may possibly account in some measure for the tardiness with which the subscriptions have come in.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

The annual meeting of the above society took place on the 13th and 14th inst. Time forbids more than a brief outline of the proceedings.

The question of co-operating with American societies in entertaining members of foreign engineering societies at the World's Fair was not favorably regarded, but was left in the hands of the council.

Mr. D. H. Keely's paper on "Developments in Telegraphy" was awarded the Gzowski gold medal.

A committee was appointed to consider and report upon the standard system of testing, and also the tests upon Canadian and foreign cement, and report at the next annual meeting.

The election of officers resulted as follows:—President, John Kennedy, Montreal; Vice-Presidents, P. A. Peterson, Montreal; W. T. Jennings, Toronto; Thomas Munro, Coteau; Treasurer, Herbert Wallis, Montreal; Secretary, Clement H. McLeod, Montreal; Librarian, Wm. McNab, Montreal; members of the Council: H. T. Bovey, Montreal; J. Jobson, Hamilton; H. G. C. Ketchum, Fredericton, N.B.; H. N. Ruttan, Winnipeg; P. W. St. George, Montreal; C. E. W. Dodwell, Halifax, N.S.; H. J. Cambie, Vancouver, B.C.; K. W. Blackwell, Montreal; C. H. Keefer, Toronto; H. D. Lumsden, Toronto; F. W. Gisborne, Ottawa; A. McDougall, Toronto; J. D. Barnett, Stafford; F. C. Gamble, Victoria, B.C.; E. A. Hoare, Quebec.

SANITARY HOUSE DRAINS.

IN dealing with the question as to the proper size of drainage pipes for houses, Col. George E. Waring expresses a decided preference for soil pipes of small bore, his own dwelling being furnished with a soil iron pipe from above the roof to outside the building line, of three-inch diameter, this being connected with the street or main sewer by a three-inch earthen sewer from the building line; there is a fall of nearly half an inch to the foot, the distance outside from the house to the main sewer being 110 feet; on this three-inch line with its two water closets, bath tub and kitchen sink, there have been during ten years' use not more than five or six obstructions, mainly due to the presence of the running trap on the main drain. In proving to his own satisfaction the inability of a three-inch soil pipe and house drain to carry off the sewage and waste matter of a private dwelling of average size, Colonel Waring does not recommend the use of three-inch pipe, but considers that a four-inch soil and drain pipe is sufficient for all dwelling houses, a four-inch being able to carry nearly 80 per cent. more than a three-inch pipe. In the same manner he declares in favor of a six-inch pipe for street sewers, though circumstances may exist where a larger pipe should be used.

BUILDING INSPECTION.

The following paper on "Building Inspection" was read last month by Mr. W. E. Doran, at a meeting of architects and students in the city of Montreal:

I will first treat of this question in its social aspect, as it is one, legislation upon which must necessarily be of a socialistic character; that is, it must be such as will control the actions of individuals in the interest of the public at large, and even in the interests of the individuals directly affected.

It is conceded that all matters affecting the safety and prolongation of life are proper subjects wherein the liberty of the individual is to be made subject to the interests of society. That man should live in healthy and safe habitations, and that the public buildings and places he frequents should be equally healthy and safe, is now an admitted axiom. In rural localities, self interest usually prompts the individuals building to in some measure attend to these points. The conditions of life, and the pure atmosphere in a great measure supply for any artificial precautions in regard to the former; and the simplicity of the construction to a certain extent ensures the latter.

It is then in cities, where the aggregation of large numbers of people, their overcrowding in particular localities and the consequent artificial modes of life therein adopted, render it incumbent that authority of some kind interfere as regards the habitations of men and their places of public resort. Thus building and sanitary precautions are to a large extent regulated by the state to civic control, and the power to legislate thereon delegated to municipal bodies. I may be considered as not keeping within the proper scope of my subject when I refer to sanitary matters; but having given the principles upon which cities affect to control building operations within their limits, I hold that a system of building inspection should be devised, which would be at once comprehensive of all the points upon which civic legislation is necessary, and which would secure as far as possible the best legislation be thoroughly enforced.

What is the first consideration in regard to a building? Site. Is it healthy? Is the soil capable of sustaining the structure to be placed upon it? If the answer to both these questions be "yes," then the work may proceed. If to both or either the answer be negative, then competent authority should say "The defects must be remedied or no building shall be erected." Here then I claim is the first matter which a building by-law should govern, and the first question for a competent building inspector to decide.

In connection with this I will add, even at the risk of digression, that no street should be built upon until the drainage therein is as perfect as engineering science can make it, and further, that at the time of constructing a public sewer, a connection should be made to each lot. Thus the soil would have some chance of being drained, rendering the site salubrious, and at the same time frequently converting bad into good building ground.

There is a good deal of attention paid now to the carrying off of sewage, to my mind mis-called "drainage"; whilst soil drainage is almost universally neglected. Though from a sanitary point of view the latter is at least as necessary as the former. Provision should also be made for completely excluding ground air from dwellings, whenever it might in the slightest degree prove injurious; also an enactment requiring the introduction of damp-proof courses in all walls.

2nd. *Light and Air.* The object for which the building is to be erected must determine the amount of [illegible] free space which it should be imperative to adjoin it on the public [illegible] street and on the property of the individual; all this should have a new by-street and on the property of the individual; all this should be provided for in a model by-law, and it should be the duty of the building inspector to see that its provisions were complied with before granting any permit to build.

3rd. *Materials and Modes of Construction.* It is universally admitted that the fundamental parts of construction should be of fire-proof material, or at least of such materials as would tend to retard the progress of conflagration. In fact the first idea of civic building inspection was founded on the prevention of fire, but as the cities progressed in wealth and opulence on the one hand, and unfortunately in poverty and degradation on the other, it has become necessary to guard against such errors of construction in the more ambitious buildings as would render them insecure, not only as regards accidents by fire, but as regards cupidity of human nature from forcing the poor to herd in unwholesome, ill-built, and ill ventilated tenements, which might at any time become fire-traps or sources of pestilence.

How can a law be framed that will cover the various and multitudinous matters that must naturally have to be decided on by the building inspector? Let it be borne in mind that no matter how competent that officer may be, to a certain extent his usefulness is marred unless the law which he is called on to administer be clear, explicit, and clothes him with sufficient authority. It is evident that to meet the requirements of our modern cities, classification of buildings must be resorted to, and for different classes, certain matters of detail must be more carefully attended to than for others. For instance: For an ordinary self-contained dwelling or small tenement, it might be sufficient that after the nature of site, light and air had been satisfactorily attended to, that a general description of the building, with details of manner and materials of construction, drainage and plumber's fixtures should be deposited with the building inspector, and that the owner should be held to notify that officer at stated periods of the work, say at its commencement, when building should be ready for plastering, and again on completion, so that officer might see that everything was in compliance with the law. More important buildings should be graded according to their future uses, their altitude, and so forth, and for these the complete plans should be deposited in the building bureau, and any details as to calculations, etc., required by the inspector should be furnished. These should be verified and if satisfactory, a permit should be issued in which it should be mentioned the various stages at which the department would have to be notified, so that the work would be properly inspected. No deviation should be allowed from the plans without the sanction of the building bureau, and further, a very important point, no building should be used for any purpose which would require a higher classification than that for which it was built, but in justice to the designers and builders, and in deference to public safety, a building should not be overloaded after a few years by the erection of additional stories, or if designed for an ordinary store, or for light manufacturing purposes, should not be exposed to the danger of caving in, or of being converted into a warehouse of the first class, or collapsing from the vibrations of heavy machinery.

In no particular should building inspection be more stringent and severe than in the matter of alterations and additions to old buildings, and if the details of the buildings to be raised or altered do not exist, and unless it can be clearly shown that the possibility of such alterations and additions was provided for in the original construction; careful examination, and if necessary, tests, should be made before the proposed improvements should be sanctioned, and in no case should the factor of safety be diminished.

Special provision should also be made as to public buildings in case of fire, modes of egress, etc., etc. These in fact are pretty generally attended to, but there is one point that is generally neglected, viz., provision to enforce proper systems of ventilation, particularly in school buildings, where children are often found to breathe for hours a vitiated atmosphere. To this cause may be traced many diseases, the origin of which oftimes puzzles physicians.

And the modern tall building, does it not call for some special attention? Is it to be allowed to tower above the reach of fire apparatus, unless constructed altogether and absolutely fireproof? Are elevators to be allowed to daily carry up and down precious loads of humanity without frequent inspection and tests? A prompt mode of dealing with existing structures which may become dangerous is also much needed, so that no one could defy the law, and one would not read as we often do after a disaster, "that the structure was condemned some years ago by the building inspector, but was nevertheless suffered to exist."

A building law should provide carefully for all these and many other details. Now how is such a law to be framed? Certainly not by a committee of aldermen with no technical knowledge, aided by an attorney of more or less legal ability, with a medical gentleman thrown in for the health points; after sitting down and making one or a half dozen conflicting by-laws on the subject, accepting such suggestions as they may think fit from their inspector. Can they hold that gentleman responsible for anything that may occur in any building, old or new, through the length and breadth of a great city, whether he had any notice of his attention being wanted in a particular locality or not, or the authority to interfere if he is aware that certain structures are dangerous? On the contrary, such a law would need long and careful study from competent men, and in its framing, our profession should certainly be consulted. I have purposely avoided anything savoring of local criticism, but I cannot resist the temptation of recording the fact that in one so-called by-law to regulate the construction of buildings in a certain city (you all know what city) no reference is made to the existence of an architect; it is altogether the owner and the builder whom the inspector is to deal with and ask for explanations. The authorities of the same city consulted the plumbers about a proposed sanitary by-law, but not the architects, who are supposed and expected to govern the former. I do not know if the same implied contempt for architects exists elsewhere, but I think I can safely assert that only with their assistance can a practical by-law be framed, which men of ability could accept, and which would be of service to those who wish to build honestly. It would also intimidate those willing to risk the lives of their fellow citizens for the sake of a slight saving of materials or labor, as it should be a penal offence to disregard in building anything which might be injurious to health or dangerous to life.

As to the officials of the building bureau, large cities should be districted, and an inspector appointed for each, who should be a thoroughly trained and experienced architect. All the accessories of building, both for sanitation and for safety should, I claim, be under one bureau, and though the details of interior drainage might be left to special inspectors, still these should be subordinates of the building inspector, and under his control. The latter should be an official in the city engineer's department. All matters relating to building, such as the giving of lines, levels, permits, etc., should be attended to at the one office, so that information or plans once given by intending builders should serve for all these purposes.

I have said that building inspection as a general rule comes under civic control, but there is properly one exception. The state must necessarily exercise a supervision over factories, and in fact should cover all public buildings where no local inspectors exist. However, in cities and towns possessing building inspectors, all general laws should be enforced by them, and the provincial or county inspectors should deal with the public only through them.

There is one point which I wish to emphasize, that is the public should not suppose that the building inspector is an architect employed by a paternal government, to take the place of the regular practitioner, and that he was obliged to give his services gratis to any one too mean to employ an architect. It should be clearly understood that the duty of a building inspector is to examine plans submitted to him, not to prepare, or give instructions for preparing them; that he has to approve or condemn, not to suggest or instruct. It is true when reviewing plans wherein some minor defects would be apparent, he might point these out, and suggest some alterations, but this should be entirely at his own discretion. Again, it would be ridiculous to suppose that the examination of a building inspector at stated times of a structure, to see that vital points were attended to, could take the place of the regular and watchful supervision of the professional architect. I would not be in favor of seeking any legislation in order to compel people to employ architects whether they desire it or not, but I think with suitable and rigid inspection those building would perceive that it was to their own interest to have the services of a competent architect.

There is one more consideration which might possibly become a subject for legislation, but it is a very difficult matter to deal with. I refer to building regulations from an æsthetic point of view. Of course it would be impossible to establish a censorship over plans, and reject those which were considered ugly. Only autocratic power, joined to absolute good taste could do this. Still when a corporation at the public expense proceeds to beautify a city with parks and squares these improve the property in their immediate vicinity, and the public has a right to exact from the owners thus benefitted, that they shall not mar what has been done. If canons of good taste cannot be made law, at least it is possible to prevent mean buildings from being erected in such localities. It seems to me that the city should have power to regulate the minimum, or even in places where it would be desirable, the uniform height of buildings in parts specially favored, even if the favors consisted only of a better class of paving and sidewalks than were possessed by the city at large.

As to erections permitted in public property, such as our own Mount Royal Park, the plans should certainly be submitted to a competent commission to decide not only if they possessed merit of themselves, but also if they were in harmony with the scene, so that man might not mar the beauty which God created.

DESIGNS FOR WORLD'S FAIR MONUMENT.

QUEBEC, Jan. 5th, 1892.

Editor CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—Through being of French descent, I might be supposed to incline to the compliment of having the Effiel tower repeated at Chicago, and as having myself been one of the competing architects for the proposed London tower, I may be supposed to have somewhat maturely considered the subject. I fully agree with the editors of the *Scientific American*, and have no doubt the general consensus of opinion will bear them out in deploring the fact that any imitation of the Effiel tower is contemplated at the Columbian exhibition. The proposed structure, an engraving of which appears in their last issue, is, or will be looked upon, as they aptly foresee, as a servile and awkward imitation of its prototype, while without any of the elegance of the latter. It is, however, satisfactory to know, if they are certain they are rightly informed, that the structure is not to be fostered by the promoters of the exhibition, but to be merely a side show for penny purposes.

If the tower must be built, let us by all means have some alteration in its outline which will give it an air of originality, be it a cone or a pyramid, or the freestums of an elongated cone, or better still, a series of superposed cylinders, decreasing in diameter, and thus leaving at each successive offset the breadth of a gallery with railing of sufficient height for security, and a floor at, say, every 100 feet, supposing this to be the height of section, with stairways and elevators around a central nucleus to reach the top—something, in a word, after the design submitted by me for the London tower. (See design No. 5 of the illustrated catalogue of the sixty eight competitive designs for the great tower for London, edited by F. C. Lynde, M. I. C. E., St. Stephens Chambers, Westminster, London, 1890). But best of all, why not carry out that grand, that novel, that almost sublime conception illustrated last year in the same journal, of a sphere surmounted by a fac-simile of the vessel in which Columbus sailed on his voyage of discovery. Then would the Columbian exhibition be truly unique and grandiose, and unlike anything the world has seen before. And with what simplicity of construction could not this be carried out, where all the parts can be made to one and the same model, if a perfect square, which it may be for simplicity and rapidity of construction, as the extra time and trouble of making the globe spheroidal, would hardly be warranted under the circumstances: the flattening at the poles being only one 300th (3¼ ft. in 1,000), an inequality between the polar and equatorial diameters which no human eye, however well tutored, could detect. And this again a form, the construction of which is so facile where the Divine architect comes to our aid in the suggestion afforded by the component ungulæ or sections of an orange.

An erect globe, while not uncomplimentary to visitors from the southern hemisphere, the equator and the tropics, as less impartial to the ideas of middle-latitudinarians, would no doubt have some popular advantages, as, in such case, the polar axis pointing to the zenith, would allow of all visitors seeing their respective meridians and the hour circles in a plane vertical or perpendicular to the horizon, as when, from any point on the earth's surface, looking towards the poles of the heavens; and this arrangement would, moreover, afford the opportunity of having the horizontal outer galleries to concord with the parallels of latitude, and, therefore, also with the arctic and ant-arctic circles, the equator, the tropics and the zones. These galleries could be easily reached from the interior by radiating footways from the aerial line, around the solid or well-like nucleus of which a double spiral stairway might extend from ground level to the top, the one ascending, the other downwards to avoid confusion, or by two or more hoists or elevators stopping on their way up and down at the several 10 degrees parallels of latitudes (87½ ft. apart as measured on a meridian), or both stairs and hoists might be used at pleasure. Nevertheless, the bulk of mankind being in the northern hemisphere, and all, or nearly all, in or near middle latitude or about half way between the equator and the pole, and as the erect globe would either place Columbus and his crew and craft, to crown the whole, in the Arctic Sea, if such there be, or lower and tilt his vessel to the latitude of the Atlantic, which would look awkward and unmonumental; it may therefore on the whole be considered best, and so that Columbus may be the crowning figure at the summit, to tilt the axis of the tiny world to true parallelism with the axis of the earth, thus pointing to the opposite poles of the heavens. With this arrangement, the stairs and elevators having to be vertical, as in the former case, would come out at top under the hulk of the vessel, and the outer galleries, if any, would, as they must naturally be horizontal, cut the parallels of latitude and other circles at an angle or inclination to the horizon equal to the latitude or elevation of the pole. And should this scheme on the scale proposed—a globe of a diameter of 1,000 ft.,—be considered too gigantic, too costly in view of the advantages to be derived, let the diameter be reduced to 500 ft., and even at this figure would the proposed sphere have a cubical capacity of some 66 millions of feet, that is, greater by about 6,000,000 than that of the greatest of the far famed pyramids of Egypt. This decrease in the total height of the structure, from 1,235 to say 617 ft., would still leave it the greatest monument of the earth, bring its features of land and sea within easier distance of the eye and more at command of the search lights from the surrounding 250 ft. towers or observatories. The interior, I suppose, would be done in imitation of the starry firmament, with incandescent lights of varied candle power to give an idea of the varied brilliancy of the stars or planets.

Yours truly,

CHAS. BAILLAIRGE,
Architect and Engineer.

PUBLICATIONS.

The announcement that Mr. Howells will leave *Harper's Magazine*, to take editorial charge of the *Cosmopolitan*, on March 1st, calls attention to the process of building up the staff of a great magazine. Mr. Howells, who is recognized universally as the foremost American of letters, upon the expiration of his contract with Harper Brothers, on the first of March will take in hand the destinies of a magazine which promises to exercise a share of influence with the reading classes of the United States. His entire services will be given to the *Cosmopolitan*, and everything he writes will appear in that magazine during the continuance of his editorship.

Messrs. Merchant & Co., of Philadelphia, have published a book entitled "What Visitors will be shown at the World's Fair by Merchant & Co.'s Brownies." In a series of excrutiatingly funny engravings, representatives of every clime are portrayed as coming to the World's Fair, where they view with amazement and much delight, Merchants & Co.'s various exhibits, consisting of roofing plates, star ventilators, sheet copper, seamless tubing, electrical supplies, spiral rivetted pipe, solders and type metals, anti friction metals, etc. After observing their various useful applications, and witnessing the prize of merit being bestowed upon them, the visitors depart for home bearing with them as souvenirs samples of the materials mentioned, and also no doubt an appreciative opinion of the ability of a firm which succeeds in combining instruction enjoyment and business profit in so happy a manner.

The Barnum Wire & Iron Co., of Toronto Junction, have found it necessary to make an assignment for the benefit of their creditors. The liabilities are estimated at $50,000, and the assets at about half that amount. A difficulty with the town authorities concerning a bonus which was promised the company but which for some cause, was never paid to them, has had much to do with the present unfortunate result.

CANADIAN CITY ENGINEERS.

III.

MR. Henry Norlands Ruttan (member Institution of Civil Engineers, member Canadian Society Civil Engineers), City Engineer of Winnipeg, Man., commenced the study of engineering on the Grand Trunk Railway in 1867.

From 1869 to 1874 he was employed on the engineering staff of the Intercolonial railway—for the latter portion of that time, as engineer in charge of section 6 on the Baie Chaleur.

In the winter of 1873 he made an extensive survey of Shippigan Harbor in connection with the proposed short line across the Atlantic.

In 1874 he was employed on exploritory surveys on the north shore of Lake Superior, on the line now occupied by the Canadian Pacific Railway between the Pic and Nepigon rivers.

In 1875-6, as engineer in charge, he made the connecting surveys and location of the proposed line of the Canadian Pacific Railway between Edmonton and the Yellow Head Pass of the Rocky Mountains.

On the beginning of construction of the Canadian Pacific Railway between the Lake of the Woods and the Red river, Mr. Ruttan was engaged by the contractor of section 15, Mr. Jos. Whitehead, as contractor's engineer, where he remained until the work was practically completed and taken over by the Government in 1880, after which he took up his permanent residence in Winnipeg and practiced his profession as civil engineer and contractor.

MR. H. N. RUTTAN, CITY ENGINEER, WINNIPEG.

The first bridge over the Red river in Canadian territory, at Emerson, was designed and built by him. The first 50 miles of the Manitoba South Western Railway was constructed for the Oregon Transcontinental Company by his firm. The first 45 miles of the Manitoba North-western Railway was constructed by him as engineer and contractor.

In 1885 Mr. Ruttan was appointed City Engineer of Winnipeg. The duties of City Engineer in a new place like Winnipeg are not very well defined; they embrace all ordinary descriptions of engineering and architectural construction, as well as the care and maintenance of all streets and public buildings and other property of the city. The most important works are the sewers. The system now contains about 20 miles, and is being extended at the rate of about 3 to 5 miles per annum. The combined system is used. In the construction the most approved modern practice is followed. All sewer connections and plumbing are regulated by by-law and carefully inspected. Pending the adoption of more permanent pavements, cedar blocks are now used.

The city bridges, two iron and one combination, over the Red and Assiniboine rivers, the city buildings, city hall, fire halls, etc., are maintained by the City Engineer's department.

The importance of a good water system being fully realized by the city council, all matters in connection with the construction and operation of waterworks and their relation to the city have engaged the attention of the council, and exhaustive examinations and reports have been made on the subject. The council has also caused investigations to be made by the City Engineer into the merits of the several systems of electric traction for street railways, and are now endeavoring to have an extensive system established in the city.

Outside the ordinary duties of City Engineer, Mr. Ruttan has made reports and estimates of cost of the drainage and development of the lands surrounding the city; on the improvement of the navigation of the Red river between Lake Winnipeg and the city; and on the utilization of the water power of the Assiniboine river—three projects which, if carried out, will add materially to the wealth and population of the city.

PLAN DESIGNING.

THE best instruction in plan design is that of examining a number of designs for any kind of building, such as we meet with in a competition. By comparing the good and the inferior plans, we begin to discover what the strong points are in the good and the weak points in the mediocre plans. We shall find invariably that the poor plans are distinguished by looseness; that they are rambling and straggling; the corridors are long and crooked; the apartments thrown here and there without any connection. The salient mark of the good plan is invariably compactness and coherency. Again we look further. We find a method in the clever plan. If there are principal rooms or departments they have been consigned to positions having some distinct relation to the site; they are prominently located along some axis, or brought to play an important part in the general design. The inferior plan has no such method or principle apparent. Comparing again the plans, we find a waste of ground in the inferior set. Here there is a large space wasted in a corridor or area; but perhaps the entrance is cramped. If the site is irregular, it is ten chances to one the author has lost space along the curved or oblique boundary, that the blocks are made to follow the boundaries, and that the angles are not at right angles. The expert plannist has taken care to make his main frontages, if possible, square, so that the main walls should be parallel, and this he does because he knows the bad effect of crooked roofs and towers if their sides appear so on main facades.

Wasteful arrangements of corridors and offices are common, and so are areas for light. But the principle of economy is only learned after some experience, and depends mainly on the principle of compactness. Much space is lost in dealing with irregular boundaries. The novice is an adept at making crooked corners and leaving spaces. He generally places his blocks parallel to the oblique sides, and in thus disposing of them creates an irregular area in the centre, spoiling the interior of perhaps a hall or some apartment. The contrary process is the course resorted to by the skilful artist. The economical designer boldly makes his main blocks parallel to one principal street or boundary of the site, or assuming an axis, to which they are made parallel. The irregular corners left between the main building and the raking boundaries are thrown out on a rear or inferior side of the area, are filled up by subordinate offices, and are left simply as areas of triangular form for light and air.

Direct and easy access, well lighted corridors, suitable proportions of apartments, and that architectural finesse which distinguishes the masterly from the crude attempt, are other characteristic elements of a clever plan, to each of which we may refer; but these are details which follow from attention to the foregoing principles.—*Building News.*

The stone for the new Toronto drill hall will come from the Deschambault quarries, near Portneuf, Quebec.

The Toronto Radiator Mfg. Co. have recently opened a branch warehouse at Victoria, B.C., in charge of Messrs. Muir & Boyd.

The Deseronto Company has been incorporated at Montreal with a capital stock of 50,000, to manufacture fire-proofing, fire brick, drain pipes, etc.

Joseph H. Farr and John M. Sparrow, of Toronto, have been granted a patent for a roofing composition consisting of petroleum tar mixed while hot with pine pitch, resin, or any other gummy substance, with or without slaked or powdered lime.

The National Brick Manufacturers' Association of the United States has appointed a committee of five to secure an international exhibition of clayworking machinery for the World's Fair. The committee have issued an address inviting the views of the trade.

HYDRAULIC CEMENTS.

THE following instructive paper, by Mr. Edward F. Ball, was read before the members of the Toronto Architectural Sketch Club, at their meeting on the 4th inst:

MR. PRESIDENT AND GENTLEMEN,—It is a popular belief that the cements used by the ancient Romans in the construction of their roads, aqueducts and other public works was superior to any in use at the present time, and that the process of its manufacture is a lost art. It may seem somewhat startling, however, to state the fact that with all the advantages they have had in hardening slowly from two to three thousand years, probably none of them is equal in strength to good Portland cement mortar made of one part cement and two parts sand *one week old*. On the shores of the Bay of Naples cement is made and used at the present day in substantially the same manner as described 2000 years ago by the old architect Vitruvius.

In remote antiquity, before the Roman era, the builders of ancient cities all over the world depended for strength and durability upon the extreme accuracy with which they dressed the surfaces of the large stones which were to be placed in contact, and also upon the bronze dowels used in uniting them. With the Romans, beside accurate stone cutting, two kinds of mortar were used. In situations where it would not be exposed to the dissolving action of the water carefully prepared lime mortar was employed, while for quay walls, aqueducts, drains, cisterns, etc., hydraulic cement was used. As is well known, ordinary lime mortar will not set under water, but if lime be mixed with clay and burned at a high temperature, a substance is formed which sets and continues to harden indefinitely, even when immersed.

The purest limes, sometimes called rich or fat limes, when freshly burned combine readily with water, which process is termed slaking. In so doing they expand, evolve great heat, and fall to powder.

Impure limes, sometimes called poor limes, do not slake so readily.

Hydraulic limes, containing a considerable quantity of clay, scarcely slake at all, and possess the property of hardening under water.

Hydraulic cements do not slake at all, and will set and harden under water.

The particles of lime have greater adhesive than cohesive force, *i. e.*, they will adhere to other substances more strongly than to each other. In hardening, mortar made from lime alone changes volume, and for these two reasons, as well as for economy, sand is used in all mortar made from lime. Good hydraulic cement does not change its volume in setting or hardening, and its cohesive strength is greater than its adhesive, so that sand is used with cement simply for economy.

Cements are divided into two classes, Portland and Natural or Rosendale.

Portland cement was first invented or discovered in 1824 by Mr. Aspdin, of Leeds, England, while experimenting with some of the over-burned clinkers of artificial cement which was then being manufactured. After pulverizing and wetting up into cakes or blocks, it became very hard and in color resembled a limestone that was being quarried for building purposes on the Isle of Portland. In taking out a patent for the new product it was named "Portland." In certain localities natural deposits of rock are found, from which Portland cement may be manufactured, but fully nineteen-twentieths of the Portland used in the United States is artificial. It is made by thoroughly mixing together in suitable proportions clay and finely pulverized carbonate of lime (either chalk, marl, or compact limestone), burning the mixture in kilns at a high temperature, and then grinding the burnt product to fine powder between ordinary millstones. In England the ingredients of the cement are mixed together with a large quantity of water and afterwards dried, burned and ground. This is called the wet process. In Germany the ingredients are mixed dry. It is very important that the ingredients be correctly proportioned, finely ground and thoroughly mixed. No substance coarser than the one-thirtieth of an inch will make cement, and the finer the ingredients are ground the better. Thorough mixing is even more important than correct proportioning, as the temperature in the kiln is not allowed to rise high enough to liquify the mass, and in order that the chemical changes may take place, the particles of lime and clay must be in close contact with each other, otherwise uncombined or "free" lime or clay will be left. In the wet way of mixing, the chalk and clay being of different specific gravities, are liable to become deposited irregularly, even under the most careful supervision. In the dry method, when the water necessary to form the mass into bricks is added, the ingredients are liable to become separated unless the water is added carefully. The first chemical change which occurs in burning is the expulsion of chemically combined water and carbon dioxide; thus calcium carbonate $Ca\,C\,O_3$ is converted into lime $Ca\,O$. The silica $Si\,O_2$ which is present as silicate of alumina in the clay, is partly transferred to the lime, forming a double silicate of lime and alumina. A high temperature is necessary for the production of this double silicate, but at a lower temperature the alumina which was present in the clay as a base plays the part of an acid, and combining with the lime, forms a tri-calcium aluminate, $Ca_3\,Al_2\,O_6$, or as it may be written $Al_2\,O_3\,3Ca\,O$. If the temperature be too high, a lime glass is formed which has no hydraulic properties, and if the burning be continued at this temperature, a solid crystallization between the silicate and aluminates of lime is formed, which does not set.

SETTING OF CEMENT.

The setting of cement is a complex process, partly chemical, partly mechanical. The chemical reactions give use to substances which as soon as formed combine with water and constitute the true cementaceous material. The tri-calcium aluminate $Ca_3\,Al_2\,O_6$ is soluble in 3000 parts of water, and in the act of setting first dissolves and then begins to separate as a mass of felted needles, consisting of calcium aluminum hydrate, which extend in every direction and are directly the cause of the first setting of the cement. At the same time an action begins which requires a much longer time for its completion, and which probably consists in a combination of the first formed aluminum hydrate with the tri-calcium aluminate and the water forming a mineral of the probable composition $H_{10}\,Ca_2\,Al_2\,Si_3\,O_{17}$. This substance crystallizes out as it forms, and this continues to add to the solidity and tenacity of the cement for long periods subsequent to the first setting. Some experiments made by the writer seem to confirm the theory that aluminum plays an important part in the first setting of the cement, and also that this is dependent in a measure upon the solubility of some of the ingredients. The experiments are as follows: Aluminum, in the form of alum (either raw or burned) added to cement and moistened, causes the mass to rise greatly in temperature, showing that a chemical change is taking place, probably the formation of tri-calcium aluminate before referred to; a sample of Improved Union cement mixed neat with water, set in 20 minutes; a sample of the same cement with two per cent. of burnt alum added, set in 8 minutes; same with 4 per cent., set in 7 minutes; same with 6 per cent., set in 7 minutes. A solution of aluminium hydrate in caustic potash produced the same effects, but in a less marked degree. It is a well known fact among cement testers that in order to get the full strength of the cement it must be thoroughly mixed and kneaded or stirred after the water has been added. This seems to indicate the presence of a soluble constituent which it is necessary to diffuse throughout the mass in order to obtain the maximum strength. If dry cement be forced into moulds under a pressure of say 70 lbs. per sq. inch, and then allowed to absorb water, a very dense, hard briquette will be formed, but it will be very weak in strength, and also very uncertain. If sufficient water be added to dry cement to properly moisten it, and if the mass be stirred just sufficiently to ensure thorough and complete moistening, and the briquette put into the moulds in the usual way, it will not be so dense or compact as if made in the way described, but will be much stronger. If, instead of slightly stirring the moistened cement, it be thoroughly turned and kneaded as long as possible before setting begins, the best and strongest briquette may be made. All this, in the opinion of the writer, points to the existence of a soluble constituent as before remarked.

IMPURITIES.

If by reason of imperfect proportioning, grinding or mixing, any portion of the lime fails to combine chemically with the silica or alumina of the clay, this is known as "free lime," and when the cement is fresh, is in the form of $Ca\,O$. Upon exposure to the air it absorbs moisture and becomes slaked, thus: $Ca\,O + H_2\,O = Ca\,(OH)_2$. Upon still further exposure it slowly absorbs carbon dioxide, and returns to its original composition before being burnt, viz., carbonate of lime: $Ca\,(OH)_2 + C\,O_2 = Ca\,C_3\,O + H_2\,O$. When present in the unslaked form, ($Ca\,O$), free lime is one of the most dangerous impurities in cement, as upon the addition of water it slakes and expands, thereby disturbing the setting of the cement. This slaking is not rapid like that of rich or fat limes, and often its effects are not apparent for the first day. It frequently happens that samples of cement will stand a good tensile strain at the end of 24 hours, while at the end of seven days the strength will hardly be greater than the 24 hours test—sometimes even below it. This generally indicates free lime, and in such a case the sample should be exposed to the air for a week and a second test made. If this test comes up to the standard, the trouble is due to the presence of free lime, and the cement may be accepted provided the other tests are satisfactory, on condition that it be spread out and exposed to the air for a week or more before use. If the lime have sufficient activity, thin cakes of the cement immersed in water for a week will become cracked, but if the lime is not present in sufficient quantity or has not the necessary activity, no cracks may appear. In order to render this test more effective, the cakes or pats may be exposed as soon as they are hard to a high temperature saturated with moisture for about three hours, and then boiled for twenty-four hours. Two per cent. should be the limit of this impurity, especially if the cement be for use under water; for use in air the presence of free lime is not so injurious, provided, of course, that it is slaked. Free lime retards the setting of cement and impairs its hydraulicity. When present in considerable quantity the cement will disintegrate on immersion, unless first allowed to become quite hard in air. In determining the amount of free lime in cement by chemical analysis, it is customary to find the amount of $C\,O_2$ on the supposition that the free lime is all in the form of carbonate, and then calculate the amount of $Ca\,O$—1 per cent. of $C\,O_2$, indicating 1.3 per cent. of $Ca\,O$. This, however, is a very unreliable method, as the lime must first be hydrated and then carbonated. This requires a long time if exposure to the air is relied upon to effect the change, as is usually the case. Hydrogen Sulphide, $H_2\,S$, is often evolved with the carbon dioxide, and this also affects the accuracy of the test.

Magnesia (in the free state) is another dangerous impurity. It may not prevent the cement from setting and becoming apparently as hard as though it were absent. For a long time it may remain inert, and perhaps for months there may be no apparent change. The magnesia, however, has an affinity for water; every two pounds of magnesia in becoming hydrated, takes up and solidifies one pound of 27.7 cubic inches of water, and in bulk every ton of magnesia would have to find room for about 16 cubic feet of water. In finding room for this water the mortar becomes disintegrated. The action continues whether in air or in water, and is especially disastrous in concrete work. Instances are recorded where concrete works have failed although built in the usual manner with cement that had stood the ordinary mechanical tests. The concrete set as hard as usual; but after a time expansion set in. In one case, a vertical wall about 35 feet high was lifted about 2½ inches, in another, a mass of concrete 16 feet thick was lifted from ½ to 1¼ inches. In both cases a white substance of the consistency of cream was seen in the concrete. On being analyzed, this substance was found to contain 80 per cent. of magnesian hydrate, consisting of about ⅔ magnesian oxide and ⅓ water. The writer made some experiments with five per cent. by weight of calcined magnesia added to Improved Union cement. The magnesia was found to render the paste very plastic and easily worked. It retarded the setting from twenty minutes to two hours, and greatly decreased the strength of the cement, as follows:

Neat cement, 1 day old, tens. strength	= 45	lbs. per square inch.
" " 1 week old, "	= 74	" "
Cement with 5% mag., 1 day old, tens. strength,	= 8	" "
" " 1 week old, "	= 19	" "
" " 2 " "	= 36	" "

At the end of one week the pats were very soft; the outside was light-grey and the interior the usual color. Good Portland cement should in no case contain more than one per cent. of magnesia.

By the rules of the "Ecole Nationale" of Paris, if the amount of sulphuric acid exceeds 1½ per cent., the cement is rejected on the chemical analysis alone.

When Portland cement is properly burned, it forms a very hard clinker, which is expensive to grind to the fineness now demanded by engineers, as the machinery requires constant repair. To render the grinding easier, iron slag meal is sometimes added to the cement clinker. This slag cement may be recognized by its lighter specific gravity (2.60) and by its color, which is a mauve tint in powder, while the inside of the water pat when broken is deep indigo. Its presence when mixed with Portland may be detected as follows: To a gill of water, add about 80 drops of sulphuric acid. Into this drop 25 grains of the cement and stir rapidly with a glass rod, and while still stirring, pour in drop by drop, a solution of Condy's fluid (64 grains of permanganate of potash to one pint of water) until the red color remains permanent. Genuine Portland will require only to to 15 drops of the permanganate solution, whilst an adulterated cement will take considerably more—30 to 60—and a cement made from slag over 200 drops. The principle of this test is as follows: Solid permanganate of potash is at once decomposed by the addition of strong acids, but in water solution this decompsition does not at once take place except by contact with oxidizable substances. This action is apparent by the change of color, the deep purple being rendered colorless. All Portland cements contain a small quantity of iron; thus with unadulterated cements a certain amount of the permanganate will be bleached, but cements containing iron in undue proportions will bleach a much greater quantity of the solution. A simple test for the same purpose is as follows: Place upon a clean silver coin a thin layer of cement, and drop on it a small quantity of dilute sulphuric acid (one acid to seven water) and afterwards rinse with water. If the cement be genuine Portland, the treatment will only slightly affect the color of the silver, but if slag be present in any notable proportion, a dark brown stain will be produced. Slag cement has been for some time manufactured in Germany, and works

have also been established for its production in England. Being a mechanical mixture of iron slag with slaked lime, it is very different in its constitution from Portland cement, which is a true chemical combination. It is stated by its inventors to be fully equal in quality to Portland cement; this, however, is not admitted by the highest authorities. Cement adulterated with slag and slag cement will be found finer ground and quicker setting than Portland, and it will attain its maximum strength in a shorter time than the best Portland, but retrogression then takes place which is most treacherous in its nature. The failure of the concrete construction of the Aberdeen harbor works is now attributed to the use of cement which was not true Portland, although at first it was considered that the action of the sea water was the cause, but examinations of similar constructions built with good Portland cement many years previously proved, that when the proper material is employed and due care exercised in construction, permanency is assured.

Salt is often added to the water used in mixing mortar in cold weather, to prevent the mortar from freezing before it has set. Authorities differ regarding the effect of salt. The most reliable information is probably contained in the report of the tests made at Governor's Island, New York harbor, by Mr. John Gartland for Col. D. C. Houston, U. S. engineer, and also of tests at the Cairo bridge. In the first mentioned tests, sea water was used, and was found to increase the strength of the cement from 1 to 80 per cent., except in the case of Hoffman Rosendale two months old. At three and six months, this same cement gave higher tests with sea water. About 330 briquettes from 8 brands of cement were tested, so the results seem entirely reliable. In the tests at the Cairo bridge the mortars were mixed in the proportion of 1 volume of cement to 2 volumes of sand. The tests were made in the manner recommended by the American Society of Civil Engineers. Each result is the mean obtained from 10 briquettes at the age of six months. The general opinion of engineers that sea water decreases the strength of cement is probably based on Gillmore's experiments, which were not nearly so comprehensive as the above.

TABLE SHOWING RESULTS OF TESTS WITH SALT AND FRESH WATER, MADE BY MR. JOHN GARTLAND, GOVERNOR ISLAND, NEW YORK HARBOR.

TABLES SHOWING THE RESULT OF TESTS MADE AT THE CAIRO BRIDGE.

BRAND OF CEMENT	FINENESS		TENSILE STRENGTH, LBS. PER SQUARE INCH				
	% passing No. 50 sieve	% passing No. 100 sieve	0% salt	2% salt	4% salt	8% salt	12% salt
Portland, Alsen's, Louisville	99.2	87.0	201	213	223	215	245
Falls City Mills,	92.4	83.5	176	179	172	146	156

Sugar added to mortar has the same effect in preventing freezing that salt has. It also combines chemically with the lime, forming a sucrate of lime, which is a detriment to cement mortar, but increases the strength of lime mortar, especially in the heart of thick walls, where lime would not harden under ordinary conditions. An excess of clay in cement is said by some to make the mortar more easily affected by frost. Over clayed cements, if underburned, set quickly and give a high test, but they are liable to injury during calcination by changes of temperature, while cement containing a slight excess of lime is not easily injured thereby.

REQUISITES FOR GOOD PORTLAND.

Good Portland should be burned at a high temperature, which is indicated by high specific gravity (95 lbs. per cubic foot) and slowness in setting (2 hours or longer). The color indicates but little, since it is chiefly due to the oxides of iron and manganese. Gray or greenish gray is considered best; bluish gray indicates a probable excess of lime; brown, an excess of clay. A mauve tint indicates adulteration with iron slag, and an undue proportion of underburned material is generally indicated by a yellowish shade, with a marked difference between the color of the hard burned ungrounf particles retained by a fine sieve and the finer cement which passes through the sieve. The fineness should be such, that 90 per cent. by weight will pass through a sieve of 2,500 meshes per square inch made of No. 40 wire (Stubb's wire gauge). Made into cakes or pats about 2½ inches square and ⅜ inch thick and immersed in water immediately after setting, it should show no cracks at the end of a week. The tensile strength of Portland cement should be about as follows, a very high strength within four weeks generally indicating an unsound cement:

COMPOSITION NEAT OR SAND	TENSILE STRENGTH LBS. PER SQ. INCH.			
	24 hours.	1 week	1 month	1 year.
Neat cement	100 to 140	250 to 550	350 to 700	450 to 800
3 parts sand to 1 part cement	——	80 to 125	100 to 200	200 to 350

It should not contain impurities in excess of the following quantities: Magnesia, 1 per cent.; free lime, 2 per cent.; sulphuric acid, 1½ per cent.; ferric oxide, 4 per cent.

ANALYSIS OF CEMENT.

Theoretically the ratio of the lime and alumina (together) to the silica should be as 265 to 100.

Combining weight of lime Ca O = 238.5
" " alumina Al_2O_3 = 26.5
265.0
" " silica $Si O_2$ = 100.0

Following are two analysis of good Portland cements, Josson and Burham:—

	JOSSON.	BURHAM.
Lime Ca O	63.60 %	61.04 %
Silica $Si O_2$	22.60	22.45
Alumina Al_2O_3	6.72	6.91
Oxide of iron Fe_2O_3	1.69	3.62
Magnesia Mg O	0.97	1.18
Potash K_2O	1.62	1.86
Soda Na_2O	——	——
Sulphate of lime Ca SO_4	——	——
Water H_2O	——	——
Sulphuric acid	1.30	1.44
Carbonic acid	1.50	1.50
	100.00	100.00

NATURAL CEMENTS.

By Natural cements are meant those which are obtained from natural stone containing lime and clay burned at a comparatively low temperature. This cement rock is usually found in several layers, containing various proportions of clay, lime, etc., and it is only by a judicious mixture of stone from the different layers that a good cement is formed. The rock is quarried, broken into pieces and burned in a kiln. The burnt cement is then crushed into small fragments and ground between ordinary millstones.

The description of impurities in Portland cement is applicable to Natural cements, except the part relating to magnesia. Free magnesia is objectionable in Natural cement as in Portland, but the greater part of natural cement rocks are argillo-magnesian limestones. In burning, a triple silicate of lime, alumina and magnesia is formed which makes a good cement, but any free magnesia will absorb water and expand as in Portland. Natural cement is generally light colored and quick setting, and is especially adapted to sewer work and places where the mortar is exposed to running water before setting. The requirements for good Natural cement are the same as Portland, except as regards color, weight, tensile strength and the presence of magnesia. The tensile strength should be about as follows:

COMPOSITION NEAT OR SAND	TENSILE STRENGTH	LBS. PER SQ. INCH.		
	24 hours.	1 week.	1 month.	1 year.
Neat cement	40 to 80	60 to 100	100 to 150	300 to 400
1 part cement to 1 part sand	——	30 to 50.	50 to 80	200 to 300

IMPROVED CEMENTS.

This name is given to Natural cements mixed with Portland. The Natural cements are usually light colored and the Portland dark, so that color of the mixture is of some value in determining the quality. It is advisable to obtain samples of the natural or "unimproved" cement, and also of the Portland used in the mixture. By comparing samples of the improved cement with these, a fair idea of its quality may be obtained.

The following tests of "Improved Anchor" cement made at the Chief Engineer's Office, Lehigh Valley Railway, will give a fair idea of the tensile strength of a good "Improved" cement:

COMPOSITION NEAT OR SAND	TENSILE STRENGTH LBS. PER SQ. INCH			
	24 hours	1 week	1 month	1 year
Neat cement	100	140	220	420
1 cement to 2 sand	——	30	75	275

Improved cements eventually attain great strength and hardness, and are but little inferior to the lower grades of Portland.

TESTING CEMENT.

On June 21st, 1885, a Committee of the American Society of Civil Engineers recommended a system of testing cement of which the following is a brief synopsis:

"It is recommended that tests for hydraulic cement be confined to methods for determining fineness, liability to checking or cracking and tensile strength; and for the latter, for tests of 7 days and upward, that a mixture of 1 part of cement to 1 part of sand for Natural cements, and 3 parts of sand for Portland cements, be used, in addition to trials of neat cement. The quantities used in the mixture should be determined by weight. Usually, when cement has a good reputation and is used in large masses, the testing of every fifth barrel seems to be sufficient; but in very important work where the strength of each barrel may in a great measure determine the strength of that portion of the work where it is used, or in the thin walls of sewers, etc., every barrel should be tested. In selecting the cement for experimental purposes, take the sample from the interior of the original packages at sufficient depth to ensure a fair exponent of the quality, and store the same in tightly closed receptacles, impervious to light or dampness, until required for manipulation, when each sample of cement should

be so thoroughly mixed, by sifting or otherwise, that it shall be uniform in character throughout its mass.

The test for checking or cracking is an important one, and though simple, should never be omitted. It is as follows:—Make two cakes of neat cement 2 or 3 inches in diameter, about ½ inch thick, with thin edges. Note the time that these cakes, when mixed with mortar to the consistency of a stiff plastic mortar, take to set hard enough to bear a one-twelfth inch diameter wire loaded with ¼ pound, and a one-twenty-fourth inch wire loaded with 1 pound. One of these cakes, when hard enough, should be put in water and examined from day to day to see if it becomes contorted or if cracks show themselves at the edges, such contortions or cracks indicating that the cement is unfit for use at that time. In some cases the tendency to crack, if caused by the presence of too much unslaked lime, will disappear with age. The remaining cake should be kept in air and its color observed, which for a good cement should be uniform throughout, yellowish blotches indicating a poor quality, the Portland cements being of a bluish gray and the Natural cements being light or dark according to the character of the rock of which they are made. The color of the cements when left in the air indicates the quality much better than when they are put in water.

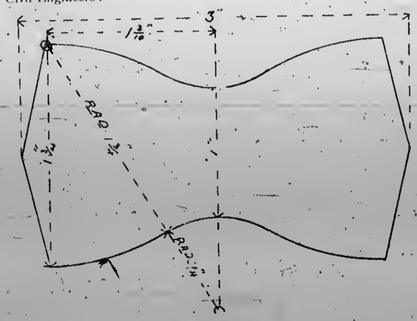
The strength of a cement depends greatly upon the fineness to which it is ground, especially when mixed with a large dose of sand. Cement of the better grades is now usually ground so fine that only from 5 to 10 per cent. is rejected by a sieve of 2500 meshes per square inch, and it has been made so fine that only from 3 to 10 per cent. is rejected by a sieve of 3,200 meshes per square inch. The finer the cement, if otherwise good, the larger the dose of sand it will take and the greater its value. Following is a table showing the results of tests made at the Cairo Bridge:

BRAND OF CEMENT.	Proportion of sand	Tensile strength, lbs. per square inch for different degrees of fineness No. 100 sieve.				
		100%	90%	80%	70%	60%
Louisville 6 months old.	Cement 1 Sand 0	320	335	318	305	349
	Cement 1 Sand 1	283	298	299	280	249
	Cement 1 Sand 2	199	192	184	173	161
Portland 6 months old.	Cement 1 Sand 0	620	621	659	692	712
	Cement 1 Sand 1	478	459	436	391	352
	Cement 1 Sand 2	322	299	263	249	224

The tests should be applied to the cements as offered for sale. If satisfactory results are obtained with a full dose of sand, the trials need go no further. If not, the coarser particles should first be excluded by using a No. 100 sieve, in order to determine approximately the grade the cement would take if ground fine, for fineness is always attainable, while inherent merit may not be. The question of a standard sand seems one of great importance, for it has been found that sands looking alike and sifted through the same sieves, give results varying within wide limits. The material that seems likely to give the best results is the crushed quartz used in the manufacture of sand paper, being both clean and sharp. The degree of fineness should be such that it will all pass a No. 20 sieve, and be caught on a No. 30 sieve. The proportions of cement, sand and water, should be carefully determined by weight, the sand and cement mixed dry and all the water added at once. The mixing must be rapid and thorough, and the mortar, which should be stiff and plastic, should be firmly pressed into the moulds with the trowel, without ramming, and struck off level; the moulds in each instance, while being charged and manipulated, to be laid directly on glass, slate, or some other non-absorbent material. The moulding must be completed before incipient setting begins. As soon as the briquettes are hard enough to bear it, they should be taken from the moulds and be kept covered with a damp cloth until they are immersed. For the sake of uniformity, the briquettes, both of neat cement and those containing sand, should be immersed in water at the end of 24 hours, except in the case of one day tests. Ordinary fresh, clean water, having a temperature between 60 and 70 degrees F., should be used for the water of mixing and immersion of samples. The proportion of water required varies with the fineness, age or other conditions of the cement, and the temperature of the air, but is approximately as follows:

For briquettes of neat cement, Portland, about 25 %
" " " " Natural, " 30 %
For briquettes of 1 part cement and 1 part sand, about 15 % of the total weight of sand and cement.
For briquettes of 1 part cement and 3 parts sand, about 12 % of the total weight of sand and cement.

The object is to produce the plasticity of rather stiff plasterer's mortar. An average of 5 briquettes may be made for each test, only those breaking at the smallest section to be taken. The briquettes should always be put in the testing machine and broken immediately after being taken out of the water, and the temperature of the briquettes and of the testing room should be constant between 60 and 70 degrees F. The following figure shows the form of briquette recommended by the Committee of the American Society of Civil Engineers:



SCALE, FULL SIZE.

GERMAN METHOD OF TESTING PORTLAND CEMENT.

In November, 1878, the Prussian Minister of Public Works issued a series of standard rules for testing Portland cement, which were adopted by nearly all the architectural and engineering associations in Germany, and subsequently served as a basis for standard rules in several adjoining countries. At the instance of the Association of German Cement Manufacturers, these rules have now been altered and several important modifications introduced. The amended rules were published by the Prussian Minister of Public Works in July, 1887, and differ from the rules previously in force as follows: The time of setting of a slow-setting cement is now fixed at two hours instead of half an hour. In testing for expansion, the cake of cement is allowed to set for 24 hours before immersing in water, during which period it is to be kept moist and in the shade. The cement must be ground so finely that not more than 10 residue remains upon a sieve of 900 meshes per square millimetre (5,800 meshes per square inch) and made of wire the thickness of which is one-half the width of the mesh; 100 grams (0.22 lbs.) of the cement is to be used for each test. The strength is ascertained by tensile and compressive tests; the cement in both cases being mixed with three times its weight of sand of a definite size of grain. The breaking area of the tensile briquette is 5 square centimetres (0.775 square inches), and the compression tests are made with cubes of 50 square centimetres (7.75 square inches). The minimum tensile strength of a mixture of 1 part by weight of slow-setting cement mixed with 3 parts by weight of standard sand, after hardening 1 day in air and 27 days under water, is 16 kilogrammes per square centimetre (227.5 pounds per square inch). The crushing strength is 160 kilogrammes per square centimetre (2275.6 pounds per square inch). The standard sand is obtained by sifting clean quartz sand first through a sieve of 50 meshes per square centimetre (387 meshes per square inch), made of wire 0.38 millimetre (0.0146 inch) diameter, then through a sieve of 120 meshes per square centimetre (774 meshes per square inch), made of wire 0.32 millimetre (0.0123 inch) diameter. The sand which remains upon the finer sieve is that which is to be used for the tests. For each series of tests ten briquettes at least must be broken; the average of the ten numbers obtained being taken as the strength of the cement. In making each five briquettes for the tensile test, 250 grammes (0.55 pound) of cement is mixed with 750 grammes (1.65 pound) of standard sand and 100 grammes (0.22 pound) of fresh water, the whole mass being well mixed for five minutes. The mortar is beaten into the moulds for one minute with a spatula weighing about 250 grammes (0.55 pound) until water begins to rise. When the surface has been smoothed with a knife, the mould is carefully removed and the briquette placed in a covered zinc-lined box for 24 hours. It is then immersed in water for the remainder of the hardening period. In making these briquettes by machinery, Dr. Bohme's apparatus is used; 180 grammes of the mortar is placed in the mould and subjected to 150 blows of a hammer weighing 2 kilogrammes (4.4 pounds). For crushing tests, Dr. Bohme's machine alone is prescribed; the proportion of water and number of blows of the hammer being the same as for tensile briquettes. All the briquettes must be tested immediately they are removed from the water. In breaking the tensile briquettes, the weight must be added at the rate of 100 grams (0.22 pound) per second. It may be mentioned that the amount of water prescribed by the German rules makes the mortar about the consistency of moist earth.

And now, gentlemen, having discussed at considerable length a very dry and dusty subject, let us enquire how it is that every manufacturer produces the best cement on the market. The reason is somewhat as follows: One of the smaller towns in Canada or the States, let us suppose, has risen to the dignity of a city, with a board of works and a duly appointed engineer, who, we hope, is a graduate of the Ontario School of Practical Science, and who is alive to the importance of carefully examining all cement used on public works. Some engineering structure of unusual importance is about to be built, and tenders for materials are asked, among other things, cement. Then up comes the great unwashed army of cement manufacturers, who, unlike their German brethren, have not awakened to the advantages to be derived from a trade union, and each deposits his tender accompanied by circulars showing that large quantities of his particular brand have been used on important works all over the country. In due time the tenders are opened, and, as usual, the figures are all closely bunched. The cement men get uneasy and anxious; but not so with our engineer. We notice an unusual gleam in his eye, and with a sardonic smile he vouchsafes the blood-curdling information that the board has ordered a testing machine. After the tests are made the contract is awarded to Mr. A., as his cement stood the highest in the tests. Then another town advertises, and the same performance is reported, and Mr. B. gets the contract, and so on from A to Z. Thus all the manufacturers are satisfied, for each has found a place where his cement stood the highest test, proving conclusively that it is the best in the market.

DISCUSSION.

During the discussion which followed, Mr. Barrett pointed out that in hot summer weather considerable quantities of sand and cement were sometimes mixed dry and stored away ready for wetting up into mortar, but this should never be tolerated, as the sand, although apparently perfectly dry, contains sufficient moisture to cause incipient setting in the cement, thereby detracting from its strength.

Mr. Wells: Why are not 24-hour tests made of mixtures of sand and cement, the same as with neat cement?

Mr. Ball: Although 24-hour tests of neat cement are useful either in themselves or in comparison with the 7-day tests, 24-hour tests of a mixture of sand and cement are of no value. 24-hour tests of neat cement, in themselves, give little or no indication of the ultimate strength which that cement will attain, but such tests are useful where a quick setting cement is required, as for sewers, in running water, &c., where quick setting is desirable, or where a considerable strain will be brought to bear soon after the cement is in place; they are also useful when compared with 7-day tests, as before mentioned. Sand does not diminish the ultimate strength of cement so much as it retards its setting and hardening, as will be seen by a comparison of the strengths of neat cement and of mortar at the ages of 7-days and one year. Mortar made with cement and sand at the age of 24-hours would possess very little strength, and would give no indication of the ultimate strength.

Mr. Johnson: I would like to ask the speaker's opinion on the practice of specifying the best quality of cement for first class masonry, and allowing inferior grades in third or second class masonry.

Mr. Ball: This is a very common mistake. Stones accurately

cut and fitted will stand without cement, as may be seen in ruins of ancient buildings, and first class masonry; with carefully laid courses, well bonded and joints dressed to half an inch for ten inches back approximates to this. But in second or third class masonry, the courses are not so carefully arranged nor the joints so accurately dressed, and more irregular pieces, such as spalls, &c., are allowed in the heart of the wall, in consequence of which the bond is not so strong as in first class, and there is more dependence on the binding power of the cement. Take concrete—where the stones in themselves have absolutely no bond at all—the very best cement is required; so, in my opinion, if any difference in the quality of cement is permissible in different classes of masonry, the best cement should be placed in that class in which the bond of the stones is least able to afford sufficient strength.

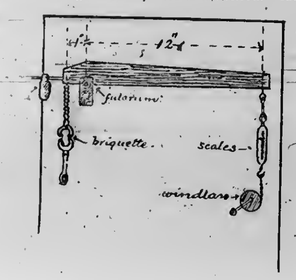
Mr. Barrett: Why are tests made of the tensile strength of cement instead of the compressive strength, which is the principal requirement in work?

Mr. Ball: It has been found by experiment that the tensile strength of cement bears a nearly constant ratio to its compressive strength—about 1-10. A very large and strong machine would be required to make compressive tests, beside which it is difficult to say at what particular weight a cube is crushed, as it splits up into smaller pieces and breaks gradually, whereas tensile briquettes break instantly.

Mr. Woolnough also pointed out that in specifying the weight per struck bushel of Portland cement it was necessary to test a whole bushel filled from a hopper placed at a certain specified height above the measure. A half or quarter bushel filled in the same manner would not be a half or a quarter of the weight of the whole bushel.

Mr. Ball stated that he did not place much value on this test, as it required a large quantity of the cement, was troublesome to make, and was only useful in indicating whether the cement was well burned or not, which could be ascertained by methods before described.

Mr. Virgil G. Marani gave an illustration of a very practical and easily constructed cement testing machine. A lever of wood is constructed, at one end of which, 1" from fulcrum, the appliance for holding the briquette is attached. At a distance,



say 12" on other side of fulcrum, an ordinary spring scales is hooked, the strain being produced by a small windlass. Therefore when scales, 12" from fulcrum, register 10 lbs. a time of fracture of briquette, the cement has stood a test of $12 \times 10 = 120$ lbs. Before making test, the weight of scales is counterbalanced by a sliding weight at *a*. This, although not an absolutely accurate method, gives very satisfactory results.

PERSONAL.

Mr. J. A. Pearson, President of the Toronto Architectural Sketch Club, is visiting parents and friends in England.

Mr. M. B. Aylesworth, architect, Toronto, is making a tour of Europe, in search of architectural knowledge.

Mr. Geo. W. Gouinlock, architect, Toronto, has recently entered into partnership with Mr. Garland, the firm name being Gouinlock & Garland.

Mr. Willis Chipman, C. E., proposes to visit Europe shortly. One object he has in view is to witness the effect of cold weather upon the operation of sewage farms in Germany.

The Hon. J. A. Ouimet has been appointed Minister of Public Works for the Dominion, and the Hon. John Haggart has been placed at the head of the Department of Railways and Canals.

The partnership recently entered into between Messrs. Smith & Gemmell and Mr. E. B. Jarvis, architects, of Toronto, has been dissolved. Mr. Jarvis has again opened offices in the Traders' Bank building.

Mr. John Galt, C. E., Toronto, has patented a steam or water heating furnace consisting of sections, with means for uniting them and providing circulation of water or steam from section to section, said sections being provided with a fire-chamber in the upper part thereof, with a stratum of water above and around the same, and flues situated beneath said chambers for conducting heated products of combustion therefrom through said section to the outlet.

OUR ILLUSTRATIONS.

NEW HIGH SCHOOL, MONTREAL.—ALEX. C. HUTCHISON, ARCHITECT.

This building occupies a block of land lying between Peel and Metcalfe streets, formerly the site of the High School building destroyed by fire over a year ago. It has a frontage on each street of about 250 feet by a depth of about 216 feet, and a height of two stories above the basement.

The basement contains the Smead-Dowd heating apparatus, coal rooms, play rooms, janitor's apartments, chemical and physical laboratories, with lecture and work rooms attached, and manual training room. The main and second storey floors contain thirty-two large and eight small class rooms, offices for superintendent, treasurer, principals, board room, &c.

The central portion of the building fronting on Metcalfe street contains a drill hall, 90' 8" × 56' 0", while the second storey of the central portion of the building, fronting on Peel street, contains an assembly hall capable of seating about 1300 persons. The building is wired throughout for electric lighting, and all the class rooms, lecture rooms, &c., are in telephone connection with the principal's room.

The elevations of the building are faced with pressed brick with trimmings of olive green New Brunswick sand stone.

HOUSES ON BAY ST. SOUTH, HAMILTON, ONT.—JAS. BALFOUR, ARCHITECT, HAMILTON.

The corner house is a reconstruction, having formerly been a cottage.

RESIDENCE OF CAPT. S. CRANGLE, ROSEDALE ROAD, TORONTO.—GORDON & HELLIWELL, ARCHITECTS, TORONTO.

"CANADIAN ARCHITECT AND BUILDER" COMPETITION FOR A SUBURBAN COTTAGE—DESIGN BY "JACK PLANE" (J. W. SIDDALL), TORONTO, AWARDED THIRD POSITION.

"METHODS IN COLORING."

Mr. Scott Morton recently read a paper before the Architectural Association on "Methods in Coloring" and commenced with the statement that "the true color-feeling is a rare thing." This talented lecturer gave in his paper a few color laws as follows: Different tones of the same color tell well beside each other or in the same composition. Take, for example, all the tints on a piece of self-colored velvet or silk. There are unending gradations of these. Much interesting work has been done on this idea on the lowest scale of color, viz., that of greys. Mr. Waterhouse expresses his predilections for pearly greys and drabs, including ivory, red or green, with very small points of delicate turquoise blue. Omitting the red or green meantime, his predilections for the pearly greys and drabs, including ivory, are well worthy of being kept constantly in mind, as these are in sympathy with the general greyness of our climate or surroundings, but it will strike all colorists that unless these tints are handled in a masterly way, there is the danger of insipidity. Mr. Scott Morton says that light is an important element in color work. If there is a direct sky light falling into the room, the reflection from the floor, which may be carpeted, counts for much, as its influence is felt on the ceiling and parts of walls not reached by direct light. He suggests for working out a color scheme, the mixing of a pot of what might be termed the dominant or key-color, and from that pot take more or less color for harmonizing and contrasting every tint employed.

One of the chief reasons for the failure of cheap houses to look well is the fact that they are overloaded with ornament. If those who wish to build cheaply would be content to build plainly, the result would be more satisfactory to the eye. The same fault is noticed in cheap furniture. It is always disfigured with fancy turns and machine carvings, while to find a piece of plain, substantial finish, one must look at the high priced goods. Too many men only able to build a cottage, load it with weak imitations of the palace, and the result is thoroughly inharmonious. In the cheap house let plainness of construction reign from foundation to gable. Let the ornamentation be, not in the wood-work, but in the painting. Then the effect may be whatever desired, and may be changed at the pleasure of the owner. —*Ex.*

American manufacturers of radiators are reported to have arrived at an understanding by which competition will be restricted.

ceased to flow and have continued dry till the present. The mill owner is now seeking for redress, but so far without success, as the Board did not enter upon any property owned by him, and did not divert any natural water course as defined by statute. Very frequently municipal corporations are mulcted in large damages for trivial acts of neglect or for expropriating property. An instance in which fortune favored the municipality is so exceptional as to be a matter of special remark and congratulation.

THE astonishment of the architects assembled at the recent convention at finding a member speaking in favor of the obnoxious term, "Registered Architect," seems to have hindered their seeing clearly that the discussion was one of words merely. Mr. Billings wanted to retain the title as being a distinctive title for the trained and educated architect. Surely the name "Architect" should be this distinctive name, as it is already in the language with honorable association as the proper title of a man who is skilled in the art of architecture. It would be a pity to leave this name by Act of Parliament to practitioners who it is generally understood are not architects in the proper sense of the term, while the man who is truly an architect can only use the title with a qualifying addition. When Bonnelleschi proved that he could build the dome of Florence and Oghiberti could not, would he have thanked the Florentines if they had for that obliged him to give up the name "Architect" to Oghiberti, and call himself a "Registered Architect"?

UNDER present conditions it seems to be a difficult matter to determine the strength of the various brands of cement on the Canadian market. The same brand will give the widest possible variation in results when tested by different individuals. In consequence differences have arisen between architects and dealers. The architect specifies that the cement shall come up to a certain standard. The dealer's tests show that the required standard has been reached. In the hands of the architect or of his clerk of works it perhaps falls short fifty or one hundred per cent. Under such circumstances we have known the dealer to request the architect to call in a disinterested third party to determine the strength of the material, but the request was refused. The honest dealer in such a case finds himself in a very unenviable position. He may have every confidence in the merits of his material to withstand a properly conducted test, but the means are not afforded him of proving his case. He is therefore under the necessity of endeavoring to procure other material in hope that it may meet with the approval of the architect, or of bringing legal action against the architect for refusing to accept material which he has reason to believe would fill the requirements if properly treated. He well knows that such a step would be likely to debar him for the future from being given the opportunity of supplying material required by that particular architect in his practice. In view of the varying behaviour of cements when subjected to tests at the hands of different individuals and by means of different methods, it has become highly desirable that there should be established by the Government one or more testing laboratories, where by payment of a reasonable fee, an authoritative test of the quality of cement and other materials could be had. We trust that full facilities for such tests will ere long be available at the School of Practical Science, Toronto, and at McGill University, Montreal.

WHEN the Toronto city council was called on a few months ago to conclude negotiations for the lease of the street railway franchise to a syndicate for a period of thirty years, it took the precaution of employing the services of legal gentlemen of high professional standing to assist in framing an agreement which should protect the city's interests. It is a singular fact that in the agreement which, as the result of this precaution, was drawn up and ratified by the Council, no provision was made for compelling the company leasing the road to adopt any improvement in methods of propulsion by electricity which in the future might be found to be more desirable than the overhead trolley. The agreement provides that the style of motor to be adopted by the company must be approved of by the City Engineer. This we take it applies to the system to be adopted when the change from horses to electricity is first made. Those familiar with the progress achieved in the application of electricity to the operation of street railways are aware, that the only satisfactory method of propulsion at present is that of the overhead trolley. It is by no means unlikely, however, that within the long period of thirty years this system will be superseded by one very much better. Care should therefore have been taken that in the event of such an improvement taking place, the city would not be under the necessity of putting up with an inferior system until the term of the lease would expire. While the terms might not have been quite so favorable to the city as at present had the council insisted that the agreement must contain a clause compelling when necessary a change of system, much better terms could have been secured before the ratification of the agreement than can be obtained now. The company is urging the Council to give its consent to the use of the overhead trolley system, and intimate that they are willing to enter into an agreement to change the system when necessary, on condition that the city will indemnify them against all loss consequent upon the change. Should the city consent to this, it is safe to say that the amoun of the indemnity which will have to be paid will be infinitely greater than the sum which would have been sufficient to effect the change prior to the signing of the agreement. The company's letter on the subject contains the significant clause that their "tender was based on an electrical system, and not on the continuation of a horse railway, and the city will fairly be responsible, not only for loss of revenue to the purchasers, but for many other items of damages incident to the unreasonable delay," should it longer delay its consent to the change being proceeded with. In short, the city is compelled either to commit the citizens to the use of the trolley for the next thirty years, or accept the company's terms for a change of system when required. That it should find itself thus situated does no credit to the discernment of those who had a hand in consummating the agreement, and least of all to their distinguished legal advisers.

THE second annual convention of the Ontario Association of Architects held in the School of Practical Science, Toronto, was a very interesting one, and in many respects was as successful as could be desired. The present number of the CANADIAN ARCHITECT AND BUILDER is largely devoted to a full report of the proceedings, with the exception of the papers and discussions thereon, which will be printed in subsequent issues. Were it not for the publication of this report, many of the members of the Association, not having been present, would be able to obtain but a very imperfect conception of the variety and importance of the business transacted. It is a matter of regret that so many of the members are unwilling to devote the small amount of time and money necessary to meet once a year with their professional brethren for the consideration of questions affecting in an important degree the welfare of architecture in this country. The architects of the city of Hamilton, although only forty miles distant, were with one exception conspicuous by their absence. It would be interesting to know what excuse they have to offer for non-attendance. Still more deserving of censure are those members of the Association resident in Toronto who did not sufficiently interest themselves in the event to put in an appearance at the meetings. Their conduct bears unfavorable comparison to that of members residing in Kingston and Ottawa. From each of these cities there were present two representatives. It was also the subject of special satisfaction to see present Messrs. Hutchison and Clift, representing the sister Association of the Province of Quebec. The interest attaching to the occasion was enhanced considerably by the harmonious character of the surroundings. Professor Galbraith, the principal, and Mr. Wright, professor of Architecture in the School of Science, spared no effort to make the visit of the architects one of pleasure and profit. The tests of materials in the laboratory were themselves a feature of much interest and value. There was also quite an extensive exhibition of drawings, which though including little with which Toronto members were not familiar, was of much interest to those from outside places.

The annual dinner at Webb's was remarkable for the variety and excellence of the speeches which the occasion called forth. The remarks of the visitors from the Province of Quebec were felt to be well considered and timely. Mr. Hutchison's suggestion regarding the formation of a Dominion Association evidently met the sympathies of a number of the members of the Ontario Society. While the majority may feel that the efforts of the two provincial organizations for some time to come will be required to be directed to strengthening their positions and putting in the way of fulfilmeot the important objects for which they were organized, it is the hope of all that eventually a Dominion Association will exist, and be the means of achieving greater things on behalf of the interests of the profession than can be accomplished by means of the present organizations. Professor Galbraith's remarks, especially relating to the strength of materials, were very instructive and valuable, while Mr. Gordon's references to the injustice done Canadian architects by the failure of the customs authorities to see that the protection designed by the tariff to be given to Canadian architects is actually afforded them, were timely and should serve to call the attention of the public as well as the Government to this important matter. From the social standpoint the dinner would have been more enjoyable had provision been made for a brief program of vocal and instrumental music. In all other respects it was a most successful affair.

Mr. W. G. Storm, who has filled the position of President since the organization of the Association, bears with him in his retirement the highest esteem of his associates. His administration has been marked by the deepest interest in everything calculated to uplift the profession, strict fidelity to duty, and the utmost courtesy towards every member of the Association. Mr. S. G. Curry, who has been appointed as his successor, has been a leading spirit in the Association from its inception, and has spared no effort to advance its interests. As President of the Association his enthusiasm and energy will no doubt continually prompt him to promote in every possible way its prosperity, and in so doing we hope he will receive the hearty co-operation of every member.

ONTARIO ASSOCIATION OF ARCHITECTS' CONVENTION.

THE second annual convention of the Association, held under the Act of Incorporation assembled in the School of Practical Science, Toronto, on Tuesday and Wednesday, the 2nd and 3rd inst. The following members were present:

Messrs. Storm, Langton, Curry, Price, Jas. Smith, Jos. W. Power, Wagner, Helliwell, Gambier-Bousfield, Gregg, Jarvis, Wickson, J. A. Ellis, Willmott, Law, McBride, Burke, Maycock, Jas. Adams, Belcher, Billings, Townsend, Whitehead, W. A. Edwards, Darling, Moore, Sproatt, Edwards, Webster, Kinsey, Gordon, Langley, Gemmell, Symons, E. J. Lennox, McCallum, Bowman, and Kennedy. Among the visitors present were Hon. G. W. Ross, and Messrr. Hutchison and Clift, of Montreal.

THE President of the Association, Mr. W. G. Storm, took the chair at 3 p.m. He regretted the fact that a large number of members had written to him expressing their inability through sickness to be present.

The minutes of the last annual convention were read by the Registrar, and after having been slightly amended, were on motion adopted.

On rising to deliver his annual address the President was received with applause. He spoke as follows:

PRESIDENT'S ADDRESS.

Gentlemen,—In opening this annual Convention of the Architectural Association of Ontario, I desire to extend the right hand of fellowship to our brethren residing at a distance from the city, to welcome them on behalf of the resident members, and to express a hope that their visit at this time may be a means of drawing us all more closely together and of promoting the interests of our noble profession. This meeting is the second held under the authority of the Act of the Ontario Legislature, which became law on the 7th of April, 1890, but the fourth since our first organization as an Association, and now that we are fully organized with a statutory constitution, it is to be hoped that our annual meetings may increasingly stimulate enthusiasm and energy, and afford profit and instruction to the older as well as the younger members of the profession, for we must never forget that, irrespective of age, we all are, or ought to be, students to the last.

Architectural students of the present day, and especially in this city, are to be congratulated on the educational advantages they possess. In addition to the carefully prepared curriculum of this Association, there are the benefits to be derived from connection with the Toronto Architectural Sketch Club in the study of architectural drawing and in hearing the lectures or talks which are given from time to time on subjects intimately connected with the practice of the profession. This Club might further extend its usefulness by establishing classes for the study of structural drawing and building construction. The lectures and drawing classes conducted by Prof. C. H. C. Wright in the School of Practical Science, I have no hesitation in strongly recommending to the consideration of all students who may be able to avail themselves of them. They are, in my opinion, the st ground work for the future study of the profession in all its ls, besides saving for the student two years study in the of an architect. It will certainly be strange if architect students are not in future good draughtsmen and learned in e various subjects appertaining to their art, for it cannot be said that ample opportunities for study, or able professors and teachers, are not at their command. I venture to express the hope that architects who have pupils in their offices will in a liberal spirit afford them every possible facilty for deriving full benefit from the exceptional educational advantages to which I have referred.

In connection with the topic of students' advantages, permit me to say a few words upon a kindred subject of great interest to the profession at large, and affecting it quite as directly as any other. I am led to refer to it because the attention of the Association will shortly be directed to the first examinations of students and candidates for enrolment on the register of the Association as fully qualified architects, which examinations will be held under our new code of laws as directed by the Act of Incorporation.

There are some who say that architecture is an art, and that as it is impossible to establish any uniformity of opinion in matters of taste it is equally impossible to set up any uniform test. This is partly true; but is this a full definition of architecture? In these days of invention and demand for scientific knowledge and treatment of every requirement of human life, building has become proportionately scientific, and the architect must accordingly be a man of education in all that pertains to constructive science. Buildings in these northern climates have to exclude severe weather and to be constantly occupied, and they must be well adapted to all the conditions of comfort and health. The architect must therefore be an expert in the nature and qualities of material and also in sanitary science. Without this he is like a student of language who has never learned its grammar, and from whom we may expect nothing but blunders.

I yield to none in my appreciation of the nobility of our calling as the embodiment of the highest form of art. But architecture is more than an art. It is an rt, a science, and a profession. And what nobler or more elevatin occupation can be conceived than to design with fitness and clothe with beauty those permanent necessities of every-day life so that each in its turn may contribute to the convenience and pleasure of mankind? The unique characteristic of our calling is, that it combines such different qualifications—artistic taste, scientific knowledge, business proficiency. We have no claim to be architects in the true and full sense of the word unless we are artists—able so to dispose and clothe the materials with which we have to deal as to produce beauty of form and proportion. But we must also be scientists, so familiar with the strength and properties of materials as to combine them in sound construction. And we must, moreover, be men of business, so conversant with affairs as to be able to protect the pecuniary trusts which are committed to us. Of what good to society would be the most graceful design in architecture if it was so devoid of constructive merit as to collapse on the first test of stability? Or conversely, what claim to architectural merit has the most perfect construction unless clothed with beauty? Architecture is composed of elements, each one of which is essential to the unity of the whole, and without any one of which it would be incomplete and useless to society. There are those amongst us whose proclivities and aspirations are specially artistic; there are those whose genius is constructive; there are those who are *par excellence* men of business. The ideal architect is the man in whom these qualities are united—who is an artist, a constructor, and a man of business. It is given to few to excel in all, though there are many who, possessing a general knowledge of each, are proficient in one or the other. And is one who is distinguished by artistic taste to regard with indifference or a species of contempt others who may be less artists and more scientific? Or is one whose genius is constructive to look askance at others who are more purely artists? No! architecture is not merely an art; it is not merely a science; it is not merely a profession; it is the combination in one of the artist, the constructor, and the man of business; and those who claim that it is one only, to the detriment of the others, detract from the nobility as well as from the unique character of their calling. They vainly strive to disintegrate things which are inseparable, and which must go hand in hand. As well seek to sever cause from effect; as well assert that neither root nor stem has any part in providing the rich foliage or the delicate flowers on which the eyes of man feast with delight.

I have been led to offer these remarks upon what I consider the true standard of the profession for the reason—as you have all been informed by circular from the Registrar—it is proposed to hold in April next our first examination in preliminary subjects, intermediate and final qualifications for full membership in the Association. The subjects which have been selected for the present examinations are not of a very abtrsuse character, as it has been deemed more prudent at this time not to be too severe or exacting in the standard of qualification, inasmuch as those candidates for membership in the Association expecting to present themselves for this ordeal have not had the advantage of previous training so as to be properly fitted for a rigid examination. But as years roll on, and the students become better educated and have greater facilities for qualifying themselves in every branch of the art and science of the profession, it is expected that the standard of qualification in the several examinations will be elevated by degrees, so that in a few years, to be a member of the Architectural Association of Ontario will be a talisman into the best kindred associations in the known world.

I indulge in the anticipation, the fulfilment of which I may not live to see, that every member of this Association will be a qualified architect in the sense of having passed an examination instituted by his brethren as the necessary qualification for membership. The affix "M.O.A.A." would in such circumstances, and in the eyes of the public, mean much more than it does now, for it could then be used only by those who had passed the test of a qualifying examination. When my confident anticipation is realized some years hence, members of this Association will be proud of their proper distinguishing letters, and will take care to relegate them to no second place, because they will be acknowledged and accepted by the public as the evidence of professional qualifications which no other letters can convey. And it is to be borne in mind also, that, to retain this privilege the architect must keep himself clear on the register of the Association, which, according to the Act of Incorporation, the Registrar is directed to revise and publish annually in the month of January for the guidance of the profession as well as information for the public.

And here I might be pardoned for digressing for a moment to refer to the series of tests of building materials which through the kind courtesy of Professor Galbraith, Principal of the School of Practical Science, have for some time past been, and are now being conducted in this building, in association with the professors of the School, by a Committee of the Council of this Association, to determine the strength of our native stone, and which will be followed from time to time by the testing of all other domestic materials used in building; these tests when completed and the results properly set forth in tabulated form, will be of inestimable value to the profession, from the fact that the tables will be more reliable as a basis of calculation than those now in general use. And there can be little doubt from the information gained in the tests already made, that there are many native stones now little known to the profession which will be brought into general use, replacing the imported stones

now so much in favor, and with—what is not the least consideration—a very material saving in the cost of building.

The Council have prepared a draft of indenture for articled clerks which has met the approval of your solicitor; printed proof copies of this have been distributed on the seats throughout the room for use of all the members in attendance at this convention. The Council request your approval of this draft and your instructions as to whether it shall be printed similar to the form in your hands or neatly lithographed. The Council have also prepared a draft form of instructions to architects, which they recommend for use in all future competitions. Proof copies of this have also been distributed throughout the room.

Our Association is now fully launched before the world of scientific institutes under the most favorable auspices. As I have remarked on a former occasion, this is the first Architectural Association in any country to obtain for its incorporation the sanction of the Legislature of the land in which it is located. But all this is of little value in elevating the profession to the standard of perfection we aspire to, unless the individual members of the profession will, by their regular attendance upon our annual re-unions—even if to do so involves some considerable personal sacrifice—add each his quota to the common fund of information and contribute from his individual store of knowledge to the interest and general usefulness of the convention, and by strict attention to the severest code of professional honor and *esprit de corps* in their individual dealings one with another and with the public, endeavor to command that respect and esteem which should be inseparable from the name of architect.

And now in conclusion permit me to extend to the officers and members of the Council and of the Association my cordial thanks for their uniform kindness to me personally, and for passing over the many deficiencies I am conscious of having exhibited during the three years I have had the honor to preside over the Association. I am nevertheless sensible of the confidence reposed in me, of which I shall ever entertain the most grateful remembrances, as being one of the proudest compliments paid me during my long professional career. In taking leave of the chair, which I must in accordance with the terms of the by-laws of the Association do at the end of this session, permit me to wish you all individually and as an Association, the fullest prosperity in your business and social relations, and I pray that the Great Architect of the Universe may grant you all health, wealth, and happiness in this world, and the salutation: "Well done, good and faithful servants" on that day when we shall all be asked to render an account of the manner in which our earthly tasks have been completed. As the poet Longfellow has it:—

"All are architects of Fate,
Working in these walls of Time,
Some with massive deeds and great;
Some with ornaments of rhyme.

Nothing useless is, or low,
Each thing in its place is best;
And what seems but idle show,
Strengthens and supports the rest.

For the structure that we raise,
Time is with materials filled;
Our to-days and yesterdays
Are the blocks with which we build.

In the older days of Art,
Builders wrought with greatest care,
Each minute and unseen part;
For the gods see everywhere.

Let us do our work as well,
Both the unseen and the seen;
Make the house, where God may dwell,
Beautiful, entire, and clean."

It was decided that as Prof. Galbraith could not be present at 10 o'clock the following morning, that Mr. Curry's paper should be the first order, and that Prof. Galbraith would be heard at eleven; and as there was no paper from any member of the Quebec Association ready, one prepared by Mr. Fuller, of Ottawa, to be read by Mr. Billings, was substituted.

Mr. D. B. Dick submitted the report of the Treasurer as follows:

TREASURER'S REPORT.

Dr.		
To balance from Association at date of incorporation		$ 172.80
To cash received from S. H. Townsend as Registrar.....	$2,351.33	
To do do W. A. Langton do	551.00	2,902.33
To refund from CANADIAN ARCHITECT AND BUILDER.....		26.00
To interest on bank a/c.....		87.22
		$3,188.35
Cr.		
By cash to Registrars' for disbursements		
S. H. Townsend.....	338.65	
W. A. Langton	494.00	832.65
By CANADIAN ARCHITECT AND BUILDER a/cs.....		82.05
By Registrar's salary (W. A. Langton, six months).....		100.00
By fee for two years refunded to widows of two deceased members.....		10 50
By balance in bank		2,163.15
		$3,188.35

We have examined the books, vouchers, etc., of the Association, and certify that the above is a correct statement thereof.

HENRY LANGLEY, } Auditors.
W. I. SYMONS, }

Mr. Dick explained that owing to the change of the date of the expiry of the annual subscription consequent on the merging of the old Association into the new, that refunds had to be made to those members who paid their subscriptions to the extent of two-fifths, and that the accounts covered a period of about seventeen months. Consequently, they did not give a fair index of what the annual revenue of the Association would be in future. There would also be the expense of conducting examinations, and it was not likely that the Association would be able to retain such a large balance at its credit as it now had.

On motion by Mr. Edwards, seconded by Mr. Smith, the above was received and adopted.

The Registrar, Mr. Langton, read his report as follows:

REGISTRAR'S REPORT.

During the year since the last convention, the Association has been established in its regular course.

The by-laws were completed, printed and distributed.

The curriculum of study for the examinations was arranged and the registered students classified according to their length of service so as to require from them only those examinations which were just; that is to say, which would permit those students who had entered into articles before the passing of the Act, to proceed to practice upon the fulfilment of their articles with as little hindrance as possible.

A Board of Examiners has also been appointed who have in charge, subject to the control of the Council, the examinations of next April.

The Association library was founded by the Council at its meeting in May, but as the greater part of the books could only be got in England, the collection was not complete enough for the issue of a catalogue before September. Since then the library has been in use by both architects and students. All members of the Association and registered students have had copies of the catalogue sent to them.

A form of indenture has been drafted and approved by the Solicitor of the Association.

Conditions of competition have been drawn up, which are submitted to the convention to-day.

Tests have been made of the building stone in use in the province, and the results will be reported.

A register of draughtsmen out of employment has been started in connection with the Registrar's office. Any student who has served his time and is in search of a position, or a draughtsman out of work, may advertise his want in this way without charge, and architects can by application at the Registrar's office select from the list of applications.

By the request of Mr. Wright, of the School of Practical Science, the Council are supporting his endeavor to establish a permanent exhibition of drawings, of which the nucleus is at present in place, at the School of Practical Science. The motive of the exhibition is primarily the benefit of the students of the School, and it is intended to be a factor in their education. But it is thought that it will also be of general advantage to the profession to have a central exhibition room where the best efforts of the profession may be displayed.

The Council has made two efforts to procure a design suitable for the seal of the Association without result. So far there have been no satisfactory designs submitted. The prize offered for the successful competitor in the competition which was advertised was $25. This sum is still offered to any one who will send in a workable design which meets the approval of the Council.

The Board of the Presbyterian Church has been endeavoring to improve the type of churches built for their body by offering prizes for the best designs for churches of different classes, a schedule of which was published in the CANADIAN ARCHITECT AND BUILDER. The money prizes are small, but there is the opportunity afforded of securing work by the exhibition of ability to do it. The Association has become connected with this venture on the part of the Presbyterian Board by their request that the Council of the Association would appoint a Committee to adjudge the prizes and report upon the drawings submitted.

I would like to remind the members that there are twenty-one members of the Association who have not paid their fees, and that in accordance with the resolution passed some little time ago, these members have not the right to vote until their fees are paid.

On motion the report was received and adopted.

The President announced the next order of business to be the consideration of the report of the Committee on "Conditions of Competition," a draft of which, prepared by Messrs. Arnoldi and Curry, had been printed and distributed.

Mr. Curry suggested that the draft be read and considered clause by clause, which was agreed to.

A lively discussion ensued in which the questions of the rendering of drawings; the nature of the report to be demanded from the experts; the definition of the commissions; the possibility of the design placed exceeding unreasonably the proposed price; and many points of precision in wording were dealt with and the draft amended in some points.

Mr. Gregg thought that the circular ought to give some definite information as to what amount of money was to be divided in prizes. The average was one-half per cent. divided into three prizes, and there should be some note bearing on this point at the end of the clause.

Mr. Curry said that it was his intention to bring up the matter when they were considering clause 14; the second, third and fourth prizes should be a definite percentage on the total cost,

and then people would know just exactly how much they would have to pay. Would one-half per cent. for the second, one-third per cent. for the third, and one-fourth per cent. for the fourth be a fair and reasonable figure?

Mr. Jarvis did not think that the public would readily consent to pay such large amounts as that.

Mr. Billings did not consider that so very far out of the way; on a $50,000 building the second man would only get $250.

The chairman agreed with Mr. Curry as to the fairness of the amounts mentioned, and the latter's suggestion that the committee should be instructed to take this matter into its consideration and report to the convention to-morrow was finally adopted. At the chairman's request, Mr. Curry named Messrs. Dick, Burke, Bousfield, Billings and himself as the committee to deal with the subject.

Mr. Curry called the attention of the members of the Association to the desirability of strictly adhering to these conditions. Some seemed to think that they were prepared for the purpose of affording a little amusement for the members. They were going to enter into competitions with others with these rules as the basis; and, seeing that as a rule, the men at the top of the profession did not bother themselves with competitions, it was for the members of the Association to say whether any member should enter any competition where these rules are not the basis of the competition. The trouble with competitions in the past had been that they had never been at all fair for the architect. There never could be a competition held that would be perfectly fair for the architects without resulting in great benefit to those holding it. There was no use meeting here from time to time and laying down conditions unless it was understood that they will be rigidly adhered to by members of the Association. (Hear, hear.) If the members of the Association did not think it worth their while to stick to matters of this kind, then they had better drop out at once. It should be definitely understood that no member of the Association would enter any competition unless it was to be conducted upon this basis. The only way to build the Association up was for the members to stick to one another; not to make it a combine to injure the public, but to unite in such a way that the union would benefit the public as well as themselves. (Applause.)

After some further discussion, a vote was taken on the wish of the meeting, and it was decided that the whole report would lie over till to-morrow morning.

When the report of the Committee on "Building Materials" was called for, Mr. Townsend, the chairman, announced that he was only able to make a preliminary report, as the tests were not yet completed. Very exhaustive tests had been conducted, with the result that all samples of stone submitted that could be broken with a pressure of 100,000 lbs., had been tested. It was found, however, that half, or nearly half, of the samples sent in could not be broken with the machine that was available. Another machine was being erected with double the capacity; this machine was nearly ready, and in a short time he expected to publish, not only the tabulated results of the tests, but also a great deal of valuable information about the quarries of the Province—their location and characteristics. This would be done in such time that it would be ready for proper presentation at the next meeting of the Association. In the meantime the members would gather from the experiments to be made by Prof. Galbraith to-morrow, something of the manner in which these tests are conducted.

The chairman announced that these tests were to be continued, and that in the course of time the results would be published.

Mr. Bousfield reminded the meeting of the question of a suitable indenture awaiting consideration.

The Chairman said that for his part he thought that the two questions of the indenture and the competition were very important questions, because, when once adopted, they ought to be permanent, and not tampered with nor changed. Perhaps it would be better to defer the consideration of them until the morning. The order for to-morrow would therefore be:—First, report of committee on premiums; second, the indenture; third, Mr. Curry's paper; fourth, Prof. Galbraith's tests.

Mr. Billings read a paper prepared by Mr. Fuller, C. E., of Ottawa, on "Ventilation in Public Buildings," which, together with the discussion thereon, will appear in a subsequent issue.

SECOND DAY.

The Association was called to order at 10:30 by the President, the first order of business taken up being the report of the Committee appointed yesterday re the filling of the blanks in regard to the premiums in the conditions for competition.

Mr. Curry announced that all the members of the Committee had not met, but part of them had, and they recommended that the first prize be one-half of one per cent., the second prize one-third of one per cent., and the third prize one-fifth of one per cent. In a competition of $100,000, that would mean that the first prize would be $500, the second prize $330, and the third prize $200.

As clause 14 was still under discussion the meeting considered the question: What course of procedure was best in case the author of the best drawing did not otherwise command the entire confidence of the experts. The discussion resulted in a slight emendation of the original draft.

The conditions of competition were then adopted as a whole, as follows:

DRAFT.

1. The ..... is proposing to erect a building, the cost of which is not to exceed ....., and have appointed a Building Committee with full power to select an architect to carry out the work.

2. The Committee has appointed M ....., architect, as professional adviser, and will appoint two other architects, nominated by the Council of the Ontario Association, to act as experts with him to decide the relative merits of the designs submitted in this competition. The two experts to be nominated by the Council will be selected from men who have no knowledge of the competition other than what they may have obtained through reading these Conditions.

3. All designs are to be made in conformity with the instructions herein given, and when it is stated that a certain requirement must be placed in a certain definite position or is to be of a certain definite size, the same must be adhered to in every particular. The competitor will be allowed reasonable latitude in planning or designing when the requirements are only stated generally.

4. The drawings enumerated in clause No. 5 are to be furnished by each competitor and these only will be received and considered; but minor variations of detail and alternative arrangements may be shown on any of the drawings by means of flaps. A competitor may omit any of the drawings called for, but it will be at his own risk, in case the experts should decide that they have not sufficient information before them to fairly judge the design in competition with its competitors. The drawings must be accompanied by a brief memorandum, typewritten, explaining any points in the design not plainly shown on the drawings.

5. The drawings required are as follows:—

6. The drawings are to be executed to a uniform scale of ..... to the foot and finished in line only, without shading, with Indian ink and with the drawing pen.

7. There is to be no brush work except in finishing the windows and sections with a solid black tint. The lettering and figuring is to be plain and simple and is to be confined to the name and dimension of the rooms, written in the middle of each, without explanatory comments, which are to be put by themselves, as has been stated, in a separate memorandum. The number of square feet in each room is to be given, as well as its lineal dimensions. The drawings are to be made upon white paper, cut down to the dimensions of ..... inches.

8. If the plans of two or more storeys are identical, all but one may be omitted, and when storeys are exactly symmetrical in plan, half only may be shown. A competitor may send in alternative elevations with any set of drawings.

9. The perspective is to be set up from an ..... scale plan and is to be drawn in line only, without shading and without any accessories such as sky, trees, figures, etc. The plane of the picture is to touch the most advanced portion of the building, and the point of sight taken from a point from which the building can be seen when erected and at the level of ordinary sight.

10. Each drawing and the accompanying memorandum is to be distinguished by a motto or cypher, and no handwriting of any sort is to be put upon either. Any of the competitors may send in a second set of drawings embodying a different plan or design if he desires to do so.—In this case it must be under a different motto. No competitor is to use any motto or device which he has used on any previous occasion.

11. A sealed envelope bearing the same motto or device and containing the address of the author is to be sent to the ....

12. The drawings are not to be framed, glazed or even mounted on cardboard, but are to be sent flat in a portfolio, and are to be addressed to ..... who will hand them to the experts in the same condition in which they are received by him with seal unbroken.

13. The experts will carefully examine all the designs sent in and place the best four in order of merit. They will also make a report on the designs sent in, but especially giving their reasons for placing the four best designs in the positions assigned to them. A copy of this report will be sent to each competitor.

14. The Committee will commission the author of the design placed first, at the regular commission, to carry out the work, provided the experts decide in consultation with them that the work may be safely entrusted to him. If the experts decide that it would not be advisable to entrust the work to the author of the design placed first, the Committee will insist that some architect in whom they have confidence shall be associated with him as consulting architect.

The author of the design placed second will receive ½ of 1%; the author of the design placed third ½ of 1%; and the author of the design placed fourth 1-5 of 1%.

15. All designs will be returned to the competitors at the expense of the Building Committee as soon as the experts have made their report. No design will be shown to any competitor nor to any other party without the consent of the author. Nor shall anything shown in any of the rejected designs or otherwise suggested by an unsuccessful competitor, which is original as to this competition, be adopted and made use of in the building without the consent of the author and proper remuneration being made him, the amount thereof to be agreed upon between him and the Committee, and in case of disagreement it is to be referred to the decision of the experts, whose decision shall be final not only in regard to the amount to be paid, but also in regard to the existence of any such claim.

16. Any information which the Committee, or any member of the Committee or their professional adviser may find proper to communicate to any of the competitors in answer to questions or suggestions, will be made in print and will be simultaneously communicated to all the rest. Such questions or suggestions must be made on or before the 15th day of ..... 189.... and must be sent to .....

Mr. Curry proposed that the "Conditions" having been carried in the Association, consisting of all men claiming to be architects in the province, (certainly with very few outside of it), should bind its members not to compete under other conditions than those of the Association.

It was then moved by Mr. Curry, seconded by Mr. Joseph W. Power, "That this convention having approved of the conditions of Competition, request every member of the Association to refrain from entering any advertised competition except those conducted under the conditions adopted by the Association."

Mr. Burke said there might be some difficulty in making this a hard and fast rule. Take the case of a School Board in the country. There are two young men in the town practising.

Each of them have friends on the Board; a majority cannot be got on the Board to decide on the architect, and a competition is decided on; then if these gentlemen were honorable members of this body it would be impossible to arrange a competition, as they would be ruled out from competing. He brought this point up for the purpose of doing away with any misapprehension in the minds of any of the members.

Mr. Curry held that such a case as the one instanced by Mr. Burke would not be influenced by the proposed action of the Association. It would not interfere with a proprietor who was prepared to build going to four architects and saying I will give $100 apiece if you will prepare competitive drawings.

The President, putting the motion to the meeting, declared it carried unanimously.

Before proceeding with the discussion of the subject of Indentures of Apprentices, Mr. Curry moved: "That the Council is hereby instructed by the Association to get the word "Registered" struck out of the Ontario Architects' Act." Section 25 of the Act says that members of the Association shall be entitled to use the word "Registered Architect," and that no other party shall use the term. Nearly every architect in the Province of Ontario was entitled to use the title, so that there were practically none who could claim to be architects outside of the Association, and if the word "Registered" was struck out, and the members of the Association given the privilege of using the title "Architect," no injury would be done to any one and the members of the Association would be in a very much better position. If the Association was to proceed with the instruction of students, hold examinations and do certain work, they should have some equivalent for that work. All such work might be done for love of the profession, but at the same time the public is receiving a much greater benefit than the members of the Association; it is really the public who are going to receive the principal benefit. None of the older men of the Association would receive any benefit, but were taking means to train up young men to supplant themselves. The young men would have good educations, be thoroughly trained and instructed, and this competition must be felt by the older men. It was only right that the legislature, acting for the people, should give some encouragement more than they had done. The Act given practically says that it is for the benefit of the public that they should distinguish between qualified and unqualified men, but practically gives the Association nothing after all. If that word could be knocked out, it would help the Association very much and would cause all to work harder for the benefit of the profession. The man who studies and works and passes his examinations should have the right to use the title, and certainly not the man who is so careless, indifferent or lazy that he will not take the trouble to become proficient. The latter should have no right to use a term which the others have acquired the right to use by hard work.

Mr. Townsend, when seconding, spoke in support of the motion.

Mr. Billings (Ottawa) spoke in the interests of those outside of the Association, and thought that the members of the Association would do better to hold on to the distinctive title "Registered Architects"—that the system of men styling themselves "architect" was in existence long before the formation of the Association and that nothing should be done to injure them; in his own city of Ottawa there are architects better than some of those who have been accepted by the Association—men with better education and training. In reply to an enquiry Mr. Billings stated that these gentlemen had not stated to him their reasons for not coming into the Association. But these men would certainly object.

Mr. Curry drew the attention of the members to the fact that any man practising as an architect has the right to come into the Association, and contended that if a man did not want to avail himself of that privilege, it was his own lookout. If the Legislature, in looking after the interests of the public, hold it to be a good thing that men practising the profession of architecture shall become educated and properly qualified to do the work that is entrusted to them, it is not then infringing upon the interests of any private individual to say that men following that profession must become educated if they desire to use the title "Architect." Up to the present time any man practicing the profession can come in. The Legislature has the right to say, "You shall not follow any profession requiring certain standards of efficiency unless you are prepared to take a course of study and pass certain examinations which will show that you are capable of doing the work properly, for the benefit of the public." (Hear, hear).

Mr. Billings stated that he did not object to wanting every man to pass an examination and to have a certain degree of competency, and that no doubt those men who would become clients of architects would desire it; but that he desired that there should be some distinctive name by which the public shall know whether these men had passed examinations or not; and contended that if a man wanted to engage the services of someone who was not a registered architect, it was a matter for the client and not for the Association.

Mr. Darling held that where it was perfectly competent for the man to join the Association if he wished, if he did not do so he ought to suffer for it, as the Association is for the public good.

Mr. Curry thought that the Association having now got in such a shape that they can give the education that the Department asked for, and having put it within the range of all who wish to come into the Association on its present standing, that the Association can now claim that they have filled their part and have done all they were asked to do, that the Council should now be given very full power to obtain the full privileges that the Association should possess. Mr. Curry stated that Mr. Darling would take his place as mover of the resolution, which would now be seconded by Mr. Wagner.

The resolution as it stood was then put to the Association: "Moved by Mr. Darling, seconded by Mr. Wagner, that the Council is hereby instructed by the Association to use their best efforts to have the word registered struck out of the Ontario Act," and was declared carried unanimously.

The Association then adjourned to witness the experiments in the testing laboratory conducted by Professor Galbraith and his assistants.

After luncheon, which was served in the building, the members met again at 2:30 p.m.

AFTERNOON SESSION.

Messrs. Hutchison and Clift, of the Province of Quebec Association of Architects, having arrived during the morning, entered the Convention at the beginning of the afternoon session and were warmly welcomed by the meeting.

The first business was the consideration of the draft form of indenture for student apprentices, printed copies of which had been distributed on the previous afternoon that it might receive proper consideration before being discussed. Several members had questions to ask or suggestions to make. The indenture was finally referred again to a Committee with instructions to make certain additions and have the indenture lithographed for distribution to members of the Association.

The Hon. G. W. Ross, Minister of Education, having entered the meeting was invited to a seat beside the President. At the close of the discussion on the indenture, the President presented Mr. Ross to the meeting amid applause.

Mr. Ross expressed the pleasure he felt in meeting with an Association composed of representatives of the profession from all parts of the province of Ontario. He sympathized very heartily with the efforts of the Association in endeavoring to give the profession a higher educational status. The legislation which he had the pleasure of promoting a few sessions ago laid the foundation for the better training of the profession; and the cordial manner in which that legislation was received by the profession was a proof that they were anxious to rank with the other learned professions of the country. He referred to the establishment of a department of architecture in the School of Science, and observed that the Ontario School of Practical Science was the only institution of the kind in the Dominion of Canada that provided special instruction in this line. Some years ago he visited the leading schools of the United States, such as Cornell, Lehigh, and the Boston Technological School, and found that the Americans had provided very liberally for education of this kind; and he felt it to be his duty to place within the reach of Canadians equal facilities. He was pleased to notice the cordiality which existed between the profession and the faculty of the School of Science, and trusted that their mutual efforts in this respect would have the effect of improving the public taste in matters of architecture and all that pertains thereto. The last few years furnished abundant evidence that in this respect there was a great change. He felt honored because of their holding their meeting in the building, and trusted that nothing would occur to mar the harmony which existed at present between the Department of Education and the Association.

Mr. Storm being obliged to leave the meeting in consequence of a business engagement, called Mr. Curry to the chair. As Mr. Storm was leaving the room, his portrait was flashed upon the wall from a magic lantern which was brought into play under the direction of Mr. Wright, of the School of Practical Science, to illustrate a talk upon house planning by Messrs. Townsend, Burke and Langton, which was the next thing on the programme. Slides had been prepared of the plans which were to form the objects of criticism and were thrown on the wall as required by the lecturers.

It was moved by Mr. Edwards, of Hamilton, seconded by Mr. Kennedy, of Barrie, that the thanks of the Association be expressed to the gentlemen who had just addressed them for the effort they had made and the trouble they had taken.

Mr. Kennedy, of Barrie, brought up the matter of taking steps to prevent the stealing of plans, etc., asking for the appointment of a committee to memoralize the Government.

Mr. Townsend believed that it would be better for Mr. Kennedy to simply request that the Council should take the matter up, and he was sure the Council would do everything necessary in the matter.

Mr. Gouinlock, who seconded Mr. Kennedy's motion as first made, agreed to the change; he had now in progress an action in this matter, and would be very glad to see some action taken.

Mr. Gordon thought that the present form of contract covered everything necessary; the plans must be returned before the final certificate is given.

Mr. Gouinlock knew that, but would like to have some remedy if possible, and trusted the council would take it up as suggested.

Mr. Bowman agreed with the preceding speakers; he had had his plans traced and used in similar buildings. He thought it was a matter which the Council should consider, and hoped for definite action.

Mr. Curry stated the motion to be that the Council should take such action as they might deem necessary to protect architects' plans, specifications and details from improper use. This was put to the meeting and carried.

Mr. Gordon mentioned that there was an instruction to the Council to prepare a blank form of certificate at the last session; he was not sure whether it was in the minutes or not, as he was not present when they were read. Mr. Langton explained that it did not appear in the minutes because the discussion came to nothing; as there was no motion carried it was not put in the minutes at all.

Mr. Curry reminded the Association that they had two members of the Quebec Association present, and thought it would be well to hear from them as to what could be done to bring the Associations closer together. He first called on Mr. Hutchison to give some information with regard to the position of the Quebec Association.

Mr. Hutchison, who was received with applause, assured the members that it gave him great pleasure to meet with this Association. The Ontario Association was the first to obtain a charter from the Provincial Government, and this fact encouraged them to try to obtain a charter from the Quebec Government. The Quebec Government had followed pretty closely the example of the Ontario Government, so that the charter of the Quebec Association contained very much the same provisions as that of the Ontario Association. In the matter of a tariff for professional services in Quebec, they were formulating a tariff which is to be submitted to the Governor-General in Council; and after it gets his approval, it becomes the legal scale of charges. Their Council had taken the matter up and, after a great deal of trouble, prepared a tariff of charges which they submitted to the Quebec Government some months ago; but the recent trouble in the Government had prevented the completion of the matter. Before this trouble arose, when they were before the Government, the question was asked, "Has the Ontario Government sanctioned a tariff of charges for the Ontario Association?" They were under the impression that it had done so, and said so. This they had afterwards to correct. So it was evident that the Quebec Government were following very much in the wake of the Ontario Government in dealing with the architects, so that a great deal would depend, as far as the Quebec Association obtaining Governmental assistance is concerned, upon what the Ontario Association obtained from their Government. There seemed to be a feeling that they would not be behind in this matter. He thought that the two Associations could work together very advantageously in the matter of obtaining the imposition of a tariff upon plans coming into this country from the United States. He looked forward with a great deal of hope to the assistance that the Quebec Association would receive from the Ontario Association in this and other matters. He had great hope that the formation of these two Associations would elevate the standard of the profession generally. (Hear, hear.) This would be a matter of slow growth; but as they compel young men who enter the profession to show a high standard of education, there was no doubt that, in the course of a few years, they would certainly elevate the tone of the whole profession. So far as it was in the power of an individual member of the Association he intended to do his utmost at all times to raise the standard to the very highest. (Applause.) They had difficulties to contend with in Quebec that perhaps there would not be in this Association. They had the dual language, though he had to say their French architectural friends had shown a great deal of interest in the Association, and he hoped they would continue to do so. He was sorry that no member of the Quebec Association had time to prepare a paper to be read at this meeting, but he could give a practical talk on the application of ventilation to hospital buildings. (Hear, hear, and applause.)

The Chairman then introduced to the meeting, Mr. Clift, Sec. of the Quebec Association, who assured the convention they did not know what pleasure it gave him to be with them. He wished that more of the Quebec members had been present. The Quebec Association had only been in existence about two years, and so had not got so many members as the Ontario Association; there were only some seventy architects qualified, and a good number of students. When they saw that an Association was being formed in Ontario, it began to be talked about by the architects in Montreal whether they could not do likewise, and bye and bye they succeeded. He took the opportunity to thank the officers and members of the Ontario Association for the assistance they had rendered him in his official capacity; they had always been willing to give him any help needed. He was sure the Council and members of the Quebec Association were heartily thankful for the assistance rendered. Mr. Clift then advocated the desirability of forming a joint association for the Dominion, with headquarters in Toronto, and local associations with officers and powers as at present. He knew it was the feeling of a great many architects in the Quebec Association, and thought the sooner it was done the better. He did not think it would be a difficult matter; provincial charters had been obtained, and a Dominion charter would be given almost as a matter of course.

The Chairman expressed the pleasure the members of the Ontario Association felt in listening to Messrs. Hutchison and Clift. With reference to the proposed Dominion Association, the Chairman thought it unwise to pledge themselves to any definite action, but thought the Association would second any efforts made by the Quebec Association.

Mr. Clift desired to move a resolution, and on being assured that members of the Quebec Association were expected and had the right to take part in the proceedings of the Ontario Association, he suggested that the two Councils should form a committee to consider the probability of forming a Dominion Association.

The Chairman thought the better way would be, as the idea originated with the Quebec Association, that they should have the privilege of taking the first step.

Mr. Hutchison stated in reply to an enquiry by Mr. Bousfield that all that his Council could do would be to consult about the matter and arrange preliminaries; it would take an annual meeting to perfect the details.

Mr. Bousfield supported the proposition, but the chairman (Mr. Curry) thought it would be as well to allow this matter to stand for a while, so that it might be discussed thoroughly. There was just one thing against it at the present time; he thought it would be better to perfect the Provincial Associations, both Ontario and Quebec, and get them running in good shape, or they would be trying to cover too much ground. They certainly looked forward to a Dominion Association, but it would be better to bring to perfection the Provincial Associations first.

Mr. Jarvis brought up the question of having as a building inspector a properly qualified architect, one who could see in a moment the merits and demerits of a set of plans, and who could readily notice points in construction.

Mr. Gouinlock did not think that this was a matter for the Association, as it concerned only the Toronto architects, and further consideration was postponed.

No further business being offered, the Chairman announced the election of three members to the Council, and suggested Messrs. Hutchison and Clift as scrutineers, which proposition was received by the Association with applause. Mr. Frank Darling, and Mr. Fuller, of Ottawa—the latter at the request of Mr. Billings—and Mr. Lennox had their names withdrawn as candidates.

While the ballots were being counted, Mr. Gordon moved that it be an instruction to the Council for this coming year that they consider the advisability of formulating a blank certificate for the general use of the profession. No action was taken in this matter by the Association.

Mr. Bousfield moved a vote of thanks to the retiring President, Mr. W. G. Storm, for the trouble he had taken during his three years of office; he had not spared time or money in his efforts for the good of the Association. He understood that Mr. Storm, under the constitution, could not be elected President for two consecutive terms, and, as he had now finished his first year since reorganization, although the third in point of fact, he was obliged to vacate the chair; Mr. Bousfield considered this all the greater reason why they should tender him a hearty vote of thanks.

Mr. Power, of Kingston, seconded the motion.

The Chairman, in putting the question, which was unanimously carried, stated that he believed a great deal of the success of the Association was due to Mr. Storm's efforts. As Mr. Storm was not present, it was arranged to formally present the thanks of the Association to him at the banquet in the evening.

Upon motion by Mr. Dick, seconded by Mr. Darling, a vote of thanks was passed to the Minister of Education, the Hon. Mr. Ross, for his interest in the Association, and to Prof. Galbraith and Mr. Wright for their assistance.

The Registrar also received the thanks of the Association.

Mr. Hutchison and Mr. Clift then announced the result of the election as follows: There were thirty votes cast; Messrs. King Arnoldi, Edmund Burke and John Belcher have a majority of all the votes cast. (Applause.)

At the suggestion of Mr. Gregg, the Chairman thanked Messrs. Hutchison and Clift for their attendance at this meeting.

THE BANQUET.

On Wednesday evening a banquet was given by the Toronto members to the visitors from a distance. About seventy persons were present. Mr. W. G. Storm, President of the Association, presided. With him at the head of the table were Mr. A. C. Hutchison and Mr. C. Clift, of Montreal, representing the Province of Quebec Association of Architects; Mr. Emerson Coatsworth, jr., M.P. for East Toronto; Prof. Galbraith, of the School of Practical Science; Mr. Kivas Tully, Architect Public Works Dept., of Ontario; Mr. Jas. Bain, Public Librarian, and others.

The *menu* was of excellent character, superior in fact to that of the previous year. After proper attention had been bestowed upon it, the President arose and in a few appropriate words proposed the first toast, "The Queen," which was heartily responded to by all present singing "God Save the Queen," followed by three hearty cheers.

"Our Sister Society of Quebec, with whom we wish always to remain on the same friendly terms as at present," coupled with

the name of Mr. Hutchison, met with a most cordial reception.

Mr. Hutchison, upon rising to reply, said it gave him a great deal of pleasure to be present representing the Association in the Province of Quebec. He would have preferred had the president or some of the vice-presidents been present, but it had not been convenient for them to do so. He had been favored with prior invitations to attend the annual banquet of the Ontario Association, but had never been able to avail himself of the pleasure of a visit until the present occasion. He thanked the Association for the very hearty manner in which they had drunk the toast to the Quebec Association, and desired to reiterate the sentiment expressed that the good feeling which at present exists between these two Associations may always continue. In Quebec, before the formation of the Association, their experience had been that the architects were like the Ishmaelites of old—their hand was against every man, and every man's hand was against them. If the formation of an Association had done no other good, it had certainly tended to remove that feeling, and was bringing the members of the profession more into contact one with another, so that they were finding that they have many things in common. No doubt the experience of the members of the profession in Ontario is very much the same. The Association has had the effect of bringing the architects in the different cities into much closer fellowship than existed before, and it is hoped that that effect will increase. The speaker said that the time may come when instead of having two Associations, there shall be an amalgamated Association which will embrace the whole Dominion, with the different provinces having their own local associations for the management of local affairs. It might be years before this could be accomplished; but he for one would do his utmost to bring about that happy consummation, and he hoped that the movement would be seconded by the profession in Ontario and Quebec. The speaker said that the first time he received an invitation to the annual banquet, while not able to attend, he wrote a lengthy letter to the Secretary expressing his hope that the Ontario profession would not stop at the formation of mere Provincial Associations, but should always aim at forming a Dominion Association. The Ontario Association being the oldest and the largest, the Quebec Association would look to it for guidance and direction in many affairs. It was largely through the fact of the profession in Ontario having obtained a charter from their Provincial Government that the Quebec architects were enabled to get a similar one passed there, and it was likely that whatever was obtained by the profession in Ontario would be obtained from the Legislature in Quebec. The speaker expressed his strong desire that everything should be done to foster good fellowship between the two Associations, and that when the Quebec Association meets in its annual gathering in October (which was a very pleasant time of the year for a pleasure trip) some of the members of the Ontario Association might be seen down there to give a cheery word and help forward the work. While the older members of the profession may not gain any great benefit from the formation of these Associations, the speaker thought that those who helped in the formation of the Associations had laid such good, deep and strong foundations for the future that the rising generation of architects will certainly be brought into a better position than was occupied by the seniors. He was glad to learn that the Ontario Association had been so far helped by the Government founding the Chair of Architecture in connection with the School of Practical Science. While the Quebec Association might not be able to look for any similar help from the Legislature of the Province of Quebec, they had great hopes that before very long they would have a Chair of Architecture established in connection with the Science Department of McGill College, which, through the liberality of two or three citizens of Montreal, has been put on the very best basis for a science education. During the past two years very large and extensive buildings had been erected especially for that department, so that now they were in a position to give a thorough scientific education. If to that they could add the art education necessary to complete the education of an architect, he looked forward to the young generation of architects being fully equipped by proper training and education to carry out the work. He did not know what kind of architects the training schools might turn out, but had no doubt they would lay a proper foundation so that a young man might be able to apply himself to any one of the three classes of work—business, constructive or artistic—or, if he had the genius, he might apply himself to all three. He looked forward with great hopes to the rising generation of architects taking a higher and better position than the seniors have done. (Applause.)

Mr. Gordon, rising to propose the toast to "The Government of Canada," said he desired to propose a toast in which all would heartily join, more especially as it was coupled with the name of one whom all rejoiced to see present that evening. He rejoiced in being permitted the honor of giving the toast of our Government, and more particularly joining with it the name of Mr. Coatsworth, member for East Toronto. (Applause). All were glad that our Government was, to a limited extent, a paternal Government. While the Local Legislature had given the Association incorporation, and the aim of the local Associations should be to obtain Dominion organization, the Association could rejoice that they had such staunch friends as Mr. Coatsworth and the other representatives of this city, and representatives from other cities who have expressed their willingness and desire to do all in their power to establish the architectural profession on a higher basis. Perhaps the only thing they could grumble at was that the Government had been a little too good to them and given them a little too much title, more than they anticipated—in giving the Association a "Registered" title. Titles generally carry some privileges with them; as the Ontario Legislature had given the Association this title, they thought the Dominion Government should give something to go along with the title; that is, a little protection—not exceptional protection. They did not want class legislation. The profession in this country was ready to stand upon the same footing as ordinary citizens in that respect, but certainly they ought to have the same protection as other citizens in the pursuit of their calling, and the laws on the Statute book should be carried out and not set aside to the detriment of their profession. The speaker referred to the customs duties in reference to taxing of plans and other professional matters coming into Canada, and claimed that the way the customs duties are now levied on plans, drawings, tracings, &c., for many important buildings was a farce. While he held that any private individual has a right to employ whoever he likes, he also contended that no public corporation, and more especially a government, had any right to go outside of its own country for that which can be as well fulfilled by those who are its own citizens and are helping to support it and should have the first claim and even the preference. As possibly Mr. Coatsworth might be called upon in his official capacity, along with the other representatives of the people, to see that this matter of the customs duty is properly carried out, it might be as well that some facts should be in proper shape for both the Government and its supporters to act upon. Many thousands of dollars are lost annually to the Government through lack of system and understanding in the appraising of plans. A man can get plans from the other side for a very important building, costing perhaps $100,000, and tracings and copies can be sent from his office and appraised at a mere nominal sum. The speaker also referred to the subject of a Dominion Association. The Provincial Associations can approach the Government and urge upon them the necessary procedure with regard to the customs duties and other matters affecting the profession at large; but if there existed a Dominion Association, with these Provincial Associations in some way in affiliation, no doubt the position of the profession would be strengthened, and they could go before the Dominion Government in a much more representative capacity and would be able to voice the opinion of the profession from one end of the country to the other. (Applause). The architectural profession perhaps comes more closely into contact with the general public to-day than any other profession—certainly conduces very largely to the comfort and prosperity of the people—and as such should receive a great deal of attention from the Government. In the future, and that before Utopia will be reached, there would be a Department of Architecture in the Government.

Mr. Emerson Coatsworth, M. P., in responding congratulated the Association upon its standing, assuring them that as a professional man he sympathized with their desire to uplift their profession, not only in the Province of Ontario, but in the whole Dominion, and stated his belief that the time was coming when the professions would be elevated to a standard of professional education so high that no inferior man would be able to hold any place with others in the professions, and no outside element would be able to compete with professional men in their own country. (Hear, hear.) He sympathized very strongly with the expressions he had heard in reference to the competition which the Association had to meet, and which to his mind was a somewhat unfair competition. It was his opinion that just as good work, and possibly better work, could be had for less money from Ontario architects than was being got at the present time from foreign architects. As to the suggestions made in regard to duties, it was only fair that reasonable protection should be afforded to architects. Industries of various kinds were protected in the Dominion, and he saw no reason why the industry of the architect should not be protected as well as the industry of the mechanic; and, as he had already promised privately to one or two gentlemen that evening, so far as he personally was concerned, he was prepared to use his influence on behalf of the architects of the Province of Ontario in order that they might be able to compete with others outside on favorable and satisfactory terms, being sure it would result in just as good work, and probably better, with less cost, and would also keep the money in our own country. (Applause.) The speaker congratulated the Association on the progress which had been made in the very few years since organization. It spoke well for the genius, industry and talent in the profession that so much could be accomplished in such a short time, and that there had sprung up among the members of the profession in Ontario and Quebec such an *esprit de corps* which leads on to greater heights, as it does all men who have that feeling among them of generous rivalry, which prompts them to be the best they can in their own sphere. He believed there was as much science in architecture as there was in law or in medicine, and that, therefore, the architectural profession should stand; as far as rights and privileges were concerned, as they do in intelligence, integrity and all other good qualities, with the other professions. When the time came that the profession was ready to form a Dominion

Association, he offered his services most heartily, and would be glad to do all he could, not only in Parliament, but also with the members of the Government who have influence in these matters, to aid in the formation of the Association. Again thanking the Association for the honor of the toast so heartily and loyally drunk to the Government of the Dominion of Canada, the speaker resumed his seat amid applause.

Mr. Dick, rising to propose the toast of "Technical Education," which was coupled with the name of the principal of the School of Practical Science, said it was quite unnecessary that he should say a single word to convince any member of the Association of the necessity for technical education; perhaps there was no profession where it was so necessary that a man should be a good all-round man in order to succeed. If an architect be not a good all-round man, he must associate with himself others who would supply the branches in which he does not excel himself. There were many excellent examples in the United States of that kind of division of labor, which perhaps after all, was the very best thing which could be had at this day, for excellence in particular departments is the only sure road to success. A man may acquire the business element by rubbing up against his fellows; the artistic he would study for himself, but the technical he had to acquire. The School of Science was being gradually developed; it had not reached its full development, but it was hoped that through the liberality of our Government, and perhaps private munificence, it would yet be placed in a position to compete with the older institutions which had large endowments and were gradually being put in positions of first-class efficiency. It was not behind any of them in one respect. It had the men, if they were only provided with the means. Something had been seen to-day of what was being done in the School of Science in the matter of providing materials for forming tables of the strength of materials. Architects had been going largely upon tables which had been constructed from experiments on a small scale, and which were unsatisfactory. The first test made in the morning showed how very erroneous some of these tables were. It was on a beam, with a cross strain, a piece of pine timber 10 x 10 inches square and eleven feet long. According to the calculations made by different formulæ, in different text books, the beam ought to have stood, before breaking, from 30,000 to 40,000 pounds; while as a matter of fact, it began to give way under a strain of somewhere about 12,000 to 13,000 pounds. The rules were made by taking a piece of wood an inch square, with a certain pressure, and multiplying both by a certain number; thus saying that if a stick one inch square would stand a certain strain, a stick of twelve inches square would sustain a proportionately larger strain. The difference was largely caused by the fact that where a stick one inch by one inch was taken, it would be practically a perfect stick, free from knots, shakes, &c., while the pieces which have actually to be worked upon might have shakes and knots, but which yet might not be so bad that the piece could be rejected and actually refused. Calculations must be based not upon the excellent quality of a piece of perfect timber, but upon the timber which actually had to be dealt with; and it was only when such machines as were now being introduced in the School of Practical Science were used so that a piece of timber might be tested, that tables could be got which would be of actual value. There was no doubt many buildings were now being subjected to greater strains than their designers intended; and that many buildings which were standing, and apparently safe, might be very near to the breaking point, but nobody knows of it until the crash comes. No doubt the testing of materials was in its infancy, and the School of Science had entered upon a career which would yet result in giving a great deal of valuable information which would be the means of enabling members of the profession to know definitely what they were doing, instead of trusting to empirical rules that might fail them at some very critical point, resulting in loss of property and, perhaps unfortunately, in loss of life, on account of the failure of some structure which, according to the calculations, ought to have been perfectly safe. The School, he was happy to say, had been organized under the care of a man whom all who knew him were thoroughly satisfied was entirely qualified for the position. They did not know where to find a better, and did not want to look for any better. The only regret they felt was that it was not possible for all the young men who proposed to be architects to put themselves under his care and go through the curriculum which has been laid down in the School. Most young men were a little too old when they left school to go through a course of technical training, and then go through another course in an architect's office. A problem which the principal and his coadjutors have to solve was how they could arrange the curriculum so as to give the young men that go into the School such a training that a comparatively short time would be all that would be necessary for them to pass in an architect's office, after they left the School, to enable them to go out into the world and announce themselves as full-fledged, capable and well-qualified architects. The company present were then called upon to drink the toast "Technical Education," coupled with the name of Prof. Galbraith.

Prof. Galbraith in the course of his response said, that he had been reminded, since they had the opportunity of using the testing machine in the School of Science, of the very little that is known about the strength or elasticity of building materials. It was laid down in the curriculum as a science which could be taught and as a thing the results of which were pretty certain, much in the same way as the science of astronomy or chemistry or other sciences, whereas it was in a very different condition. In astronomy the positions of the various planets could be calculated beforehand, and in chemistry, the results might be known beforehand. But how little could be said about the strength of any member of construction! It seemed marvelous that a science so intimately connected with safety and comfort, and in which we have the experience of all the ages, should be practically no science at all. The principles that are settled in the science of materials can be summed up in a very few words. Then when they are applied you have to multiply your results by the thing called the "Factor of Safety," which has been well called the "Factor of Ignorance." Instances of that were seen this morning. According to the formulas the beam should have been twice as strong as it really was. Very few who had not seen experiments conducted on the same scale, could have said anything about it at all. So it was throughout the whole range of the science of strength of materials. When a young man begins to study the strength of materials he asks, "What is the breaking strength of a certain material?" which shows the misconception which attaches to the whole subject. When he came to look into it a little more closely he would find there was no such thing as the breaking strength of any material, in the proper sense of the word. A piece of pine or steel might be broken in an infinite number of ways, and under all sorts of strains, while the question just spoken of implied there was only one. It was known that the rods in a railroad bridge or a roof truss might last for years and then break down; that test of practical service and the test in a testing machine were entirely different. Strains can be applied to a piece twice, and a less strain will break it applied a second time, than when applied only once. Another strain could be applied three, four or ten times and be less than the strain which was applied once or twice. This could be multiplied an infinite number of times. He had no hope that the science of the strength of materials would ever be developed to such an extent as to enable them to build with the factor of safety of one, that is, that they would be able to design a piece to last under such conditions as those under which it would be intended to be used, a certain number of years and then break down. Although they knew all about the material, and had carried on the experiments that would determine the various breaking strains of the material, they were entirely ignorant of what force a structure would be subjected to after being built, so they would always have to apply the factor of safety—the factor of ignorance. They would, possibly, not be factors of ignorance at the end of a thousand years, as to the material, but would be still factors of ignorance as to the possible forces to which the material would be subjected. Machines had been invented in Germany by which repeated stresses could be applied to the same material. To give an example as to how often these repetitions take place, the speaker asked them to consider the case of one of the tie-rods in a Howe truss railway bridge. Suppose that in a bridge where, the traffic being very great, a train might cross the bridge every quarter of an hour through the whole day; that would make about 100 repteitions of that strain in the twenty-four hours, that multiplied by 300, to get the number in a year, would make 30,000 for the year; if the bridge should last twenty years then it would be 600,000 repititions of the stress. To investigate properly the strength of that piece, it ought to be subjected to at least 600,000 repetitions of the stress caused by the train passing. To do that under the proper conditions would require twenty years; life is too short for that; and the Germans had repeated this strain every minute, instead of every quarter of an hour. Even that required over a year to make the one experiment on the one rod, and then you know only the result for that kind of material and nothing else. That would give some idea of what investigation into the strength of materials meant; they would never see the end of it; those who live generations after would not see the end of it. Then it had to be remembered that there were all kinds of strains and stresses to structures. The machines which they had in the schools were only the modern development of the old-fashioned machines which determined only one kind of breaking stress, the stress which is produced by a load which is gradually increased up to the breaking point, and only applied once. They were utterly unable with their equipment to make experiments like the German experiments; they could not be done very well by steam power, because the firemen and engineers have to be at work day and night; the only possible way of doing it is where they have water power which could be set going and would not require very much attention, but would run on until the piece broke. So that although they were making great advances, they were precluded, in the School of Science, from their position, from going into the question to the extent to which they could elsewhere and under other conditions. At the same time by a judicious use of the factor of safety, they could make great use of the results, in designing. They would no doubt be able to reduce the factor of safety on some materials. The speaker was pleased to see that professional men were taking an interest in the School of Practical Science, and felt that it could be of some use to them; the only justification of the expense to which the Government had gone in fitting out

this School was that it put the architectural and engineering professions in touch with science. It was not proposed to go into it as a matter of amusement in any way. Meetings like those which had been held in the last two days strengthened the School with the Government and also did an immense amount of good to the students. Nothing would make the young men take more interest in their work than to see the older men in the profession interested in it; that was one of the greatest benefits that could be gained from meetings like the present. He had urged this upon the authorities and was happy to say that the Minister of Education, especially, had always shown himself open to argument in that respect. He had urged that the interruption to the immediate work of the School caused by these meetings was as nothing as compared with the benefits to the students. They could afford to let the work go a day or two for the sake of the stimulus and life that meetings like these put into their young men, and he hoped that meetings of all professional men connected with the work of the School would, in the course of time, be held in the School—that they would make that a gathering point. They had done that in Montreal; in McGill College the Faculty of Applied Science had done everything that they possibly could to bring the civil engineers, the mechanical engineers and the electrical engineers into connection with their school for the same reason; and that was the only true policy. It is a school that lays the scientific foundation for a practical education. They wanted this sort of thing, and to feel themselves working in the same lines, doing the work in the same lines as the professions, and helping them. After thanking the gentlemen for the kind way in which they had received the toast, the speaker resumed his seat amid applause.

Mr. Curry said he was called upon to propose the next toast, and as it was in reality to one of their guests, he would on this occasion reverse the order, because after all what they were particularly interested in was not the Public Library, but the librarian. As all were aware, Mr. Bain had taken a great deal of interest in the Architects' Association and in the profession, which interest he had shown in the trouble he had taken to place at their disposal the architectural works in the Library as far as it was in his power. He is also using his best efforts to have a room arranged, when additions are made to the Library building, where architects may freely consult the valuable professional works now in the Library. No doubt all here are aware that any member of the Association by applying to the Registrar can consult at the Registrar's office a great number of the architectural works which belong to the public library. It was not necessary that the speaker should enlarge upon the benefit this was to an architect; if he could have a work which he desired to look over, in a room by himself, with plenty of time and opportunity for the use of drawing materials, it was of very much greater benefit to him than if he had to go to a public institution where he could only work at a disadvantage. The Association was indebted, and all were personally indebted to the librarian for what he had done in that respect. The members of the Association could best show their appreciation of the efforts of the Public Librarian, Mr. Bain, by making, as far as possible, full use of the facilities which he had placed within their reach. He called upon all to drink to the health of Mr. Bain, Public Librarian.

Mr. Bain, replying, said he was very grateful to the proposer for the kind words which he had spoken. He was very deeply interested in the library, and looked on this act as an approval of his course during the last eight years and as a presage of their support for the future. He had given himself twenty years in which to make the Public Library; eight years had already gone by and he thought they had made a fair start. He had hardly realized that it had assumed the position it had until this morning when they had received from the English Government a series of papers in reference to the Duke of Clarence's funeral addressed to the "Public Library, Canada, British North America," and they were delivered to the Toronto Public Library. (Laughter and applause.) Some four years ago he had been exceedingly anxious that they should have a special architectural and fine arts room, and proposed that the room should be fitted up entirely for works of architecture and the fine arts, so that gentlemen who were anxious to examine books and large plans could do so, and have opportunities of looking at books on kindred subjects, such as stained glass, carving, etc., that would be necessary in their work. Unfortunately it required a great deal of effort to get the municipal body to move; however, two years ago he had succeeded in getting it passed, and had everything planned out for a very nice room when the matter was referred over for a few months. Plans were talked over, but just at that time, unfortunately, the people in the Argentine Republic took it into their heads to kick up a row. Messrs. Baring Bros., the people who floated the bonds for the Public Library, failed, and left them without money. He had been very pleased a short time ago at receiving a visit from Messrs. Langton and Darling to talk over the matter again, to see if it was possible to afford any room in the present building. He was afraid, owing to the pressure of books now, that it would be impossible, but he thought within twelve or eighteen months they would be able to provide it, and not only double, but treble their books on architecture. They were buying all the time, and never allowed a book, especially an expensive book, to pass. The cheaper books could be bought by architects for use in their offices day by day, but the expensive books that a man only occasionally wishes to look over, books which in many cases are the works of architects themselves, printed in small numbers and issued in their own offices. He hoped that the accumulation would be such that it would be satisfactory to the members of the Ontario Architectural Association.

Mr. Langley arose to propose a toast "To the Old Times and the New, in Architecture." He supposed that topic had been put in his hands to propose because he was considered to be getting to be one of the old heads. He accepted it as a compliment. He could look around on the company present and see many who had passed through his office—many of them now leading architects of the Province. It was a cause of sincere pleasure on his part. 38 years, lacking a month, had passed over since he went to serve his time; many changes had taken place in that period, and not the least among them was the marvellous advantages the pupils of the present day had as compared with those of thirty years ago. He was deeply gratified that two of his own sons were attending the School of Practical Science, with which Prof. Galbraith is connected, and having the advantages of the training which is to be obtained there. He had seen the profession increase in Toronto from about seven firms to nearly ten times that number. In connection with the toast he called on their friend, Mr. Kivas Tully, one very highly respected and very long in the profession, for a few words.

Mr. Tully in responding asked whether he was to represent the old times or the new. He was still in practice; he commenced serving his time 55 years ago, and it was for those present to say whether they would have the old times or the new. He should have liked to have had a young associate to support him under the great obligation of returning thanks for the new as well as he would try to do for the old. He had served his time in the old country and came here in 1844, when he found about four other architects here—Mr. Howard, the City Engineer, Mr. Thomas, Mr. Young and his (the speaker's) brother, who was serving his time in Mr. Howard's office, and himself; those were all the architects at that time in Toronto. He did not know how many there were at the present time, but he supposed about one hundred. He had to congratulate the profession upon having improved so much and having become such a promising body. He was sorry to say he was the only living representative of those five architects. He hoped that in the future the rising generation would do as good work as had been done in the past. (Applause). He had been very much pleased to hear the remarks which had been made by Mr. Dick and Prof. Galbraith upon the strength of materials. He advised the younger members not to skimp their work in any way, but to have plenty of strength.

The President called upon Mr. Clift, of Montreal, who responded with a few well chosen remarks for the "New Times."

Mr. Curry stated that he had a matter to introduce which had been postponed at the afternoon meeting. He had to inform the President that, in his absence that afternoon, while he (Mr. Curry) was occupying the chair, the Association passed a vote of thanks for the very great pains and trouble to which he had gone during the past three or four years to help forward the interests of the profession and the Association. The mover and seconder of the resolution and also several members of the Association had spoken very highly of the work which the President had done, and it was a very great pleasure for him now to also state that having been a member of the Council during the time Mr. Storm had been President, he could substantiate any statement which had been made as to the interest he had taken in the Association and the amount of work he had done on its behalf. In no particular had he shirked his duty, and had always been pleased to do all that lay within his power to assist the Association with his sympathy and also by actual work. By so doing he had benefitted the Association to a very great extent; it was work which possibly no one else could have done in as satisfactory a manner. He now desired to express to the President the thanks of the Association for what he had done in the past, and a wish that although under the by-laws and constitution of the Association, he cannot be the president for the following year, that in some other year or years he may be again at the head of the Association. (Applause). The speaker concluded by calling upon the Association to drink to the health of the retiring President and his success.

The toast was heartily responded to.

The president, responding to the toast, returned his thanks for the honor conferred and the eloquent remarks of Mr. Curry in proposing the toast and informing him of the resolution which the Association had so kindly passed after his departure from the meeting that afternoon. What little he had done to forward the interests of the Association during the past few years had been done with the greatest pleasure, and he felt that the appreciation of them was far beyond their value; what he had done would have been of no advantage to the Association had he not had with him a first-class working Council and also a first-class Registrar during the whole term. (Applause). These gentlemen were entitled to more praise than he was, for their untiring energy and devotion to the interests of the Association.

Mr. Jarvis proposed the toast to "The Ladies," coupling therewith the name of Mr. A. C. Barrett, who in graceful periods eulogized the fair sex. This brought to a fitting close a thoroughly enjoyable evening.

CANADIAN CITY ENGINEERS.

III.

AQUILLA Ormsby Graydon, City Engineer of London, Ont., also claims that city as his birth-place, having been born there in July, 1854. He is the eldest son of the late Simpson Hackett Graydon, B.A., T.C.D., of Dublin, Ireland, but practising barister in London, Ont., since 1853.

The subject of our sketch was educated at the public and grammar schools of London. In 1870 he entered the Merchants' Bank of Canada, having filled the positions of junior ledger-keeper, teller and accountant. He left the Bank in 1874 to become paymaster for Mr. Wm. Hendrie, contractor, of Hamilton, Ont., in connection with his contract for building the Wellington, Grey and Bruce railway from Listowel to Kincardine, and was in his service for four years, until all his railway contracts were completed, when he returned to London and articled himself to Messrs. Robinson & Tracy, both former City Engineers of that city. He studied engineering and architecture with them for four years, taking the degree of P.L.S. in his third year (1881).

Mr. Graydon was engaged on the construction of the London waterworks during 1882, and in 1883 opened an office for himself. He was appointed engineer of the townships of London, Delaware, Dorchester, East and West Nissouri and Biddulph, also of the London Provincial Line Road Co. Subsequently he laid out the Brampton, Ont., waterworks, and supervised the construction thereof until nearly completed.

In 1888 he was appointed Assistant City Engineer of London, and received the appointment of City Engineer in July, 1891, on the resignation of Lieut.-Col. T. H. Tracy, who was offered and accepted the City Engineership of Vancouver, B. C.

MR. A. O. GRAYDON, CITY ENGINEER, LONDON, ONT.

TORONTO BUILDERS' AND CONTRACTORS' ASSOCIATION.

A VERY enjoyable time was spent at the second annual dinner of the above Association, held at Webb's restaurant on the evening of the 11th inst. Nearly one hundred members and invited guests were present.

Mr. Geo. Wright, President of the Association, occupied the chair, being supported on his right and left by the Mayor and Mr. Joseph Tait, M.P.P. The vice-chairs were occupied by Mr. J. Lester Nicholls and Mr. David Williams.

Letters of regret at their inability to be present were read from Mr. E. F. Clarke, ex-Mayor, and Mr. John Webb, President of the Builders' Association of Hamilton.

The usual loyal and patriotic toasts were duly honored, Mr. Tait responding in happy style to "Our Legislators," and the Mayor to "The City Council." The latter took occasion to remark, that considering the importance of the building interests, and the frequent introduction of legislation in the City Council affecting these interests, he was surprised that the Association did not, as other organizations had done, appoint a committee to watch the proceedings of the Council.

"The Old Association" was responded to by Mr. John Lucas, and Mr. Wm. Booth, President of the first Association organized by the builders of the city some twenty years ago, and ex-Alderman Farquhar.

Messrs. John Aldridge and M. Murphy replied on behalf of "The New Association," and Messrs. Moir and Goddard on behalf of "Kindred Institutions."

Excellent songs were sung by Messrs. J. Lester Nicholls, R. G. Kirby, H. M. Blight and F. Self, while Messrs. H. K. Cockin and O. A. Smiley favored the company with well-rendered recitations.

Credit for the success of the gathering is largely due to the committee of management, Messrs. Geo. Wright, D. Williams, J. Aldridge, J. Claxton, J. Goddard, J. Crang, J. Lester Nicholls and F. Powell.

It is understood that the Association is to some extent being reorganized on an improved basis. The annual meeting will take place next month.

TORONTO ARCHITECTURAL SKETCH CLUB MEASURED DRAWINGS COMPETITION FOR "CANADA COMPANY'S PORCH"—DRAWING BY "VOLUTE" (MR. W. P. OVER), AWARDED FIRST POSITION.

PUBLIC SCHOOL, GLADSTONE AVENUE, TORONTO.—STRICKLAND & SYMONS, ARCHITECTS, TORONTO.

PASSING EVENTS.

I heard a sermon recently from the text "Build yourselves up in your most holy faith." On the whole the subject may be said to have been well handled. After pointing out that every man is the builder of his own moral structure, the speaker proceeded to describe some of the requisites of a good building, such as a good design, a good plan, a good foundation, good materials, etc. Having sately got this far, he was tempted to go farther and illustrate his subject by directing the attention of his hearers to a building embracing all the requisites of good architecture. He pointed to his ideal in language somewhat like the following: "Take, for example, the new Parliament buildings in Queen's Park. As we enter them a glance at the long halls, large assembly rooms, etc., shows their adaptability to their purpose, while as we view their exterior we are lead to exclaim, 'Our sense of beauty is fully satisfied.'" I am charitable enough to presume that the preacher's religious ideals are of a higher order than is his artistic perception.

What resident of Toronto is not ready to express his gratification at seeing the sum of $20,000 placed in the estimates of the Parks and Gardens Committee of the Council for the improvement of the approaches to Queen's Park? I would like to entertain the hope that stone—artificial or otherwise—and asphalt will shortly take the place of the dilapidated cement sidewalk and macadam roadway which for the past decade have marred the beauty of Queen's Avenue. It is to be hoped the newly installed Council's anxiety for retrenchment will not lead them to apply the knife to this very necessary appropriation.

PASSERBY.

VALUE OF WATER WORKS.

From the Eighteenth Annual Report of the city of Grand Rapids, Mich., some insight into the financial value of water works can be gained. The report says:

"No credit has ever been given to the water works system for fire protection, which makes it appear at the first sight that the water system does not make a good financial showing. But taking into consideration the reduction of insurance rates on the residences, manufacturing plants, and all property liable to destruction by fire, it clearly shows that a water plant is the best paying investment that any muncipality can make. To illustrate: Information from insurance headquarters shows that the amount of property insured in this city is from $20,000,000 to $22,000,000. The rates of insurance are from one-fourth of one per cent. to five per cent. per annum. Before the establishment of the present efficient fire department and the existence of our water system rates of insurance were from one per cent. to ten per cent. per annum. From the same source we learn that the amount of property insured is equally divided between low and high rates, and that the average in insurance is fully two per cent., in consequence of the facilities for extinguishing fire. This would make a saving to our citizens of at least $40,000 per annum from this source alone during the past year."

PRESBYTERIAN CHURCH COMPETITION.

FOR the benefit of draughtsmen who are occupied before April upon the work of the Association examinations, the time for rending in drawings for this competition will be extended to May 21st next. All drawings must be marked by a motto or cypher, and the name and address of the designer enclosed in envelope bearing the same mark.

Dr. A. M. Rosebrugh, of Toronto, has patented a "Combined window ornament and ventilator," which consists of a short supplemental sash secured to upper window sash. This presents a direct draft over this upper sash when the same is lowered a few inches and provides for an indirect draft through the syphon-like space formed by the overlapping of the upper and lower sashes. This fans a gentle current upwards towards the ceiling and promotes the diffusion of fresh air without perceptible draughts. The supplemental sash may be plain glass, colored glass or bevel plate, and may be adapted to any building, new or old. When secured to the outside stops they do not interfere either with outside shutters or with winter sash. A company is being formed to operate the patent.

HOW TO ESTIMATE.

By W. H. Hodson.

FOLLOWING is a portion of the specification and bills of quantities accompanying the drawings of Public School on Gladstone Avenue, Toronto, appearing in this number. The balance of specification and quantities will be printed in next issue.

EXCAVATION, &C.

Do all excavation required for the basement and foundation of building to the dimensions shown and figured on the drawings, making the same 12' clear of the outside of footings of all outside walls. The excavation for basement and foundation walls, &c., to be taken out to the depth required, and level in all directions for footings and floor. The spaces outside of the outer walls to be kept clear of earth until the masonry has been properly pointed up and inspected and passed by the architects. The spaces around the outside of walls when directed by the architects are to be filled in with earth and the same well rammed and consolidated. The surface of ground around the building is to be cut and filled to the grade lines laid down by the architects, and in all cases so as to give a fall of at least 3 ins. in every 12 ft. outwards. The whole surface of lot as shown per block plan is to be cut and filled and graded to an uniform grade throughout, the earth arising from the excavations and cuttings being used for that purpose, so far as may be required, and the surplus earth (if any) carted from the premises.

DRAINAGE.

Provide and lay down all drainage as shown by the foundation plan, and in the most thorough and workmanlike manner, complete in all respects. Provide for and pay for 9 in. sewer connection from street sewer to street line. Provide and lay down 9 in. drain from point shown on plan to sewer connection, and provide and lay down 4 in. and 6 in. drains from the points shown on plans connecting with the 9 in. main drain, and with all proper Ys, bends, elbows and junctions and traps, &c., complete. Provide and lay down 3 x 4 in. common or weeping tile drains under basement floor, and connect same to the leading drain from basement. The drains are to be laid with best quality of American salt-glazed or Scotch vitrified drain piping, with socket joints connected with Portland cement, and to be laid with an uniform and sufficient fall, in no case less than ½ in. per foot run of pipe. Care must be taken that every pipe is firmly bedded and packed so as to prevent settlement after the grade is fixed. The drains from water leaders are to turn up within 2 ft. of the surface to receive the same, and to be firmly packed in position and the mouth covered until the conductor pipes from roof are connected. Weeping drains are to be carefully laid in trenches prepared for same, and when laid to be packed around with fine broken brick and coarse gravel, and to have all connections made in the most careful and thorough manner. No drain is to be covered up until inspected and approved by the architects.

MASONRY.

The stone for footing courses and rubble masonry is to be of best quality of large sized Lake and Humber stone, in about equal quantities, and the "coursing" above grade lines to be built with Credit Valley grey stone. The mortar is to be composed of the very best quality of fresh burnt stone lime and clean coarse sharp grit sand in the proportion of 2½ parts of sand to one of lime, mixed with a proper quantity of clean water, and all well and thoroughly incorporated and tempered together. No "soft" or "loamy" sand will be allowed in the work. Lay the footing courses as shown and figured on sections with selected large flake stone thoroughly bonded and bedded firmly in mortar. Build up the foundation walls in good rubble masonry from top of footings to level of basement ceiling, to be 16 in. in thickness, built to a line on both sides and in 15 in. courses, in height corresponding to five courses of brickwork, and so as to bond with the inside brick lining to same as shown per plans and sections. The masonry is to be thoroughly bedded and bonded, each and every stone laid on its natural bed and "through-bonds" built in every 5 ft. on each course. The masonry is to be built plumb, square and true, on both sides of every wall, and to a fair face, and to be thoroughly flushed in at all beds and joints, and neatly pointed with the trowel. The outside face of *all outside* walls is to be plastered with a heavy coat of "cement mortar," composed of one part of best Portland cement to two parts of coarse and clean grit sand, properly tempered with water and laid on fresh as required, and not less than one-half inch in thickness, laid on evenly. The foundation walls above grade line will be faced with Credit Valley grey coursing of selected large stones, built in random coursed work in four courses of one foot each for the large blocks and the random work made up in front two to three stories. Each and every stone to have picked beds and joints, and to have a bed of not less than once and a half its vertical height. Every stone in the coursed work to have a clean and fresh rock face, free from all stains, flaws and other defects, to be hammer dressed to reveals of all windows, doors and other openings to same, and to have an inch margin draft of tooled work on all corners. The coursed work is to be pointed with cement mortar composed of Portland cement, Smith's ashes and lamp-black, and each and every joint to be well cut and weathered and finished in very best manner. The foundations to two large vent and smoke stacks are to be laid with Dimension stone in two courses of eight inches in thickness, each properly bedded in mortar and thoroughly bonded, no stone being less than 4 square feet. Provide and lay *two* footing courses of 6 in. thickness under all internal brick partition walls, and one thickness of same under the brickwork of all "brick-setting" to heating apparatus and flues, as shown per plans, all built in the most substantial manner. Also lay one course of similar footings under the outside area entrance ways and steps, &c., all complete and as above described. The whole of the masonry is to be built with the best of materials called for, and in the most substantial and workmanlike manner, complete in all respects.

CARPENTER AND JOINER WORK.

All the wood work used throughout the building, play sheds and fencing (except otherwise specified) is to be of the best quality and description of white pine, free from sap, shakes, dead, loose and large knots, wane and other defects, and to hold to the dimension specified and figured on drawings, and to be well seasoned. Immediately the contract is awarded, the contractor will proceed to and procure all joisting and other dimension stuff, and have same on the ground ready prepared for the building as the works progress. In same manner all door and window frames are to be prepared in proper time and made ready for setting in the work as the same progresses. All window sash to be made and fitted at same time as frames are made, and then delivered to the glazier at his shop for glazing, who at the proper time will deliver the same at the building ready for carpenter to hang. All doors are to be got out loosely knocked together and stacked away in a drying house until required in the building, when they are to be properly cramped up, wedged and glued, fitted and hung to all in best manner. All doors, sash wainscoting, stairs, and other finished stuff throughout the building, including all door and window frames, etc., is to be of the best quality and description of clear and thoroughly kiln dried pine, all well cleaned up after passing through the machines, and when fitted, to be left clean and in thoroughly good order to receive the painting. Ground and first floor joists to be 14" x 2" set 16" centres, the corridor and attic joists to be 12" x 2" set 16" centres. Provide and fix three sets of chain joists to the floors of the four upper class rooms (12 in all), built of two 14" x 2" joists with 1⅛" packing piece between, all well spiked together and with 1⅛" iron straining rod, 6"x8"x¼" end plates, and well threaded nuts and washers complete. These joists to be bolted together with ¾" iron screw bolts, with nuts and washers, 12 bolts to each chain joist. Trim for stair wells, ventilating stacks and hot air flue, with double 14" and 12" x 2" joists double tusk frames and spiked together, and for stairwells to be strengthened at the corner with 2 in. x ½ in. stirrup pins. Provide and fix wrought iron anchors to ends of chain joists, also to attic joists directly over the same, to be 2 in. x ½ in. x 3 ft. in length, turned up 6 in. at one end and built into brickwork, and the other end bolted to joists with two ¾ in. screw bolts. There will be 48 of these anchors required. Trim the attic joists for manhole in same over the ceiling of teachers room, and provide and fix 2 in. frame in same, 26 in. x 30 in. rebated and fitted with 1¾ framed and panelled door, hinged on top with 4 in. butts and secured with ½ in. iron stay-hook 3 ft. long. Provide neat dressed step ladder of 1¼ in. strings and 2¼ in. steps strongly made for access to above manhole. The joists throughout to be laid level for floors and ceiling, and to have not less than 4 in. bearing on walls, and well spiked to bond timber in wall. The basement and ground floor ceilings will be counter ceiled with 2 in. x 3 in. and 2 in. x 2 in. strapping, set 16 in. centres and properly levelled for ceilings of same and well spiked to under side of joists with 4 in. spike to each joist in the most secure manner. Provide and fix 4 in. x 2½ in. well seasoned bond timbers to receive floor joists, also across under all window openings and for basement do. to be dressed on the face and set fair with the brickwork. Provide and set 6 in. x 8 in. well seasoned pine lintels to all windows and door openings in outer walls except to basement windows which will have double lintel same size dressed on the under face and soffet. The doors in partition walls will have double 6 in. x 6 in. lintels, and in basement to be 6 in. x 6 in. and 6 in. x 8 in. laid together and dressed on the face and soffit to finish fair with face of brickwork. Provide and set 2½ x ½ well seasoned bond strip to all outer walls every 6th course in height for strapping and grounds, also provide and build in 9 in. x 14 in. x 3 in. well seasoned jamb blocks to all door openings, 8 to each opening. Provide and set well seasoned wood bricks of 3 in. stuff to all window openings except basement. Provide and strap all outer walls except in basement with 2 x 2½ in. well seasoned pine strapping set 16 in. centres and well spiked to bond strips in walls, the strapping to be set true and plumb to line on the face to receive the lathing. The sliding door between the two upper class rooms to have a 10 in. x 14 in. well seasoned and dressed pine lintel over same and trussed on top with 4 in. x 8 in. Queen truss with inch foot and suspension rods, with nuts and washers, etc., all complete. Provide and set 3 in. x 12 in. solid and moulded door frames to the front and rear entrance with 3 in. oak weathered sill rebated and fitted for 2½ in. thick raised panelled and bolection moulded doors. The rear entrance ground floor door to have 4 x 6 in. moulded transom bar and 2¾ in. moulded transom esoh, basement entrance doors to have upper half fitted for glass as shown per elevation with 1¼ in. sash base. The inside doors to front porches to be 2¼ thick and as described for the front entrance doors. Provide and fix 2 in. x 15 in. solid and moulded door jambs with moulded transoms and transom sash, and 1¾ in. thick panelled and solid moulded doors complete. The front entrance doors to be 4 ft. x 8 ft. in 6 panels, hinged with three 8 in. square wrot. iron black japanned butts and fastened with heavy and neat forged iron latches with twisted ring shambles bolted on and secured with 6 in. carpenter's locks, and held open with ¾ in. round iron hook and staple all complete. (For sample of above latches, see those on Ryerson and Given St. schools.) The ground floor rear entrance door will be same size and hinged and fastened as above described. Basement entrance doors to be 6 ft. 8 in. x 3 ft. 6 each and 2¼ in. thick, panelled and moulded in the solid on stile and rails, and fitted for glass, to be hinged with two 6 in. wrought iron butts and fastened with 6 in. carpenter's lock with 2½ in. black japanned or brass knobs, and to have hold back hooks as described for front doors. All class room doors to be 7 ft. 6 in. x 3 ft. 4 in. x 1⅝ in. thick, six panelled and moulded in the solid on stile and rails, to be hinged with 6 in. square wrot. iron black japanned butts and fastened with heavy mortice locks (Griffith's gravity locks per sample in office) and fitted with 2½ in. finished brass knobs complete. These doors will have 1¾ in. moulded transom sash over same fitted with two lights of glass 18 in. x 24 in., to be hung on vertical centre pin sitting and secured with a steel spring catch, and to be fitted with a counter sunk finger plate. Provide and fix 2¾ thick framed and panelled sliding door between closet rooms, as shown per drawings, to be formed in 12 panels having 8 in. wide outside stiles, 6 in. wide intermediate stile, 8 in. wide top and middle rails and 12 in. wide bottom rail; the three centre vertical stiles are to be 1½ in. thick, only the centre panels being counter sunk as one large panel 15 ft. x 3 ft. 6 in. high to receive the blackboard, and when same are set to be held in by small hardwood stop ¾ in. thick, set flush with the stile and rail, and fastened with round head screws. This sliding door to have ¾ in. half round metal rail screwed to floor and extending across the corridor and to be fitted with two best pattern 6 in. turned sliding door wheels with turned steel axle and bushings, and screwed and counter sunk into bottom rail all complete. Provide and fix 2 in. jambs to sliding door opening and to sliding door slit in corridor, well moulded, etc., and provide and fix 2 in. x 6 in. moulded pine boxing to one side of sliding door opening to side and head of same. The doors into privy closet rooms in basement, also into coal rooms and furnace rooms, six in number, will have 6 in. x 3 in. chamfered and rebated frames and 2 in. oak sills, fitted with 4 in. transom bars and 1¾ in. transom sash, to have 1¾ in. x 3 ft., 6 ft. 8 in. doors hinged with 5 in. wrot. iron black japanned butts and fastened with 6 in. x 4 in. carpenter's locks and 2½ in. brass knobs, same as to class room doors. The two lunch rooms in basement will not have any door frames or doors. Provide and fix 2 in. door frames and 1¼ matched and cleted doors 5 ft. x 2 ft. 3 in. to four air chamber in privy rooms, also similar frames and doors to ventilating stacks, frames to be 6 in. x 2 in. chamfered. Also provide similar frames and doors to upper part of ventilating stacks above attic floor, and provide and hang same with 10 in. T hinge, and fasten with 6 in. barred bolts. Provide and fix 6 in. x 3 in. solid and chamfered frames and 1¼ moulded sash to all basement windows, the sash to be hinged on top with 4 in. butts and fastened with 6 in. barrel bolts, two to each sash, and to have stout pulley cord, and plumb bob balance weight fastened to ceiling to open and shut same. Provide and fix borrowed light frame 8 in. x 3 in. with ¾ in. vertical iron bars 4 in. apart in same to corridors in basement where shown on plans, four in number complete, to be 3 ft. 6 in. and 4 ft. Provide and fix boxed frames to all class rooms and corridor, windows, grooved and toqued together, with 2½ in. beads and sills and fitted with double hung 1¾ in. moulded sash fitted for 6 lights, 14 in. x 24 in. to each sash or 12 lights to each window. The corridor windows to have 18 x 24 glass. All the above mentioned sashes to be double hung with best Silver Lake braided cotton sash line, iron weights 2½ in. solid axle turned pulleys, and each sash to have two metal lifts and one metal counter sunk pull down fitting; and one good heavy metal sash lock. Provide eight brass pull down hooks, fitted to

light ash poles, one for each class room complete. Provide large half-circle window frame of 6 in. x 3 in. stuff, with 4 in. x 4 in. mullion bars. And 1¾ moulded sash to gable window with inside stop, etc., complete. Also similar circular frames to porch and rear gable windows, the former to have inside inch bead planted around the cural. Provide and construct the roof to building and porches, etc., as shown per elevations and sections. The main roof is to have 12 in. x 3 in. wall plates, 8 in. x 2 in. rafters, 10 in. x 2 in. hip rafters, and double 10 in. x 2 in. valley rafters well spiked together with 4 in. spikes. The rafters will be 18 in. centres, notched down on to will plate and ridge and deck plates and well spiked to same with 4 in. spikes. The deck roof to be supported with framed "Bents," as per sections 12 in. x 6 in. x 4 ft. templates bedded on top of corridor walls, and upon same the framed "Bents" to rest, having 8 in. x 8 in. sill and head piece, 8 in. x 8 in. posts, 6 in. x 6 in. streets, and 6 in. x 8 in. purlins, also 8 in. x 2 in. cross ties, the latter spiked to side of posts and common rafters with 5 in. spikes, the common rafter being doubled opposite each "Bent," the bents also to be braced with 6 in. x 4 in. braces and to leave 8 in. x 8 in. plates extending along from bent to bent and bolted and spiked to same with ¾ in. iron bolts and 4 in. spikes, to receive the ends of rafters. These "Bents" are to be mortised and tenoned and pinned and spiked together in the most substantial manner, and where necessary, the head pieces to extend out far enough beyond the post to give support to valley and hip rafters. The roof to be covered with good sound and seasoned grooved and tongued flooring 1¼ in. thick all well nailed, and breaking joints every 6th board, the flooring to be 6 in. wide and laid close at joints, and to be free from large, loose and dead knots. Trim and line the ends of rafters to receive the roof cornice, and provide and put ⅞ in. faced to same, and ⅞ in. x 10 in. matched soffit lining and 6 in. moulded bed moulding and 6 in. crown moulding and 1½ in. core moulding under crown and gutter moulding of 9,000 sound and well seasoned stuff, all well dressed, fitted and nailed and laid in first-class order for painter. Provide and fix role pieces of ⅞ in. and 6 in. stuff and 3 in. round and rebated ridge rolls all well spiked on and all dressed for painting, also provide and fix ½ in. thick by 4 in. slate grounds, bevelled tilting pieces to vallies and eaves as may be required by slater. Construct gables as shown, with moulded cornice to same, also gablets at open of main roof, next to ventilating stacks, with moulded cornice, etc., complete. Provide and construct roof to belfry as shown, to have 6 in. x 3 in. plate and 6 in. x 2 in. rafters, and ⅞ in. grooved and tongued boarding, and shaped brackets to receive the galvanized iron moulded cornice, all well spiked together, and fitted and secured to brickwork. Provide and construct stair from ground to first floor, as shown per drawing, to have 2¼ in. thick moulded strings and three 6 in. x 4 in. carriage pieces. Steps of 1⅛ in. pine risers and 1⅛ in. oak treads housed at ends into well and wall strings and well wedged and glued, etc., and to be well blocked to carriage pieces. The rise of tops to be 6½ inches and treads 10½ in. with ¾ in. fall or pitch to latter, and to have rounded and moulded risings. The balustrading at side of stairs to consist of ⅞ in. by alternate 3 and 4½ in. grooved and toqued and bevel jointed sheeting nailed to the side of well string and capped with a 6 in. x 4 in. oval backed oak hand rail ploughed out to receive the ends of sheeting and to have quarter round moulding planted along under same. The balustrading around the well at top of stairs to be constructed in same manner, the sheeting to be nailed to side of well trimmer joists and finished on the inside and at ceiling line with ⅞ in. ogee moulded plinth, also to floor line in same manner and to correspond with the wall wainscoting, with quarter round moulded shoe strip, etc., all well nailed. Construct rest-landing to stairs as shown per plans, with 10 in. x 2 in. joists built into corridor wall and floored with ⅞ in. oak flooring with 1¾ in. moulded nosing of same corresponding to tread of stairs. Post 6 in. x 6 in. chamfered on angles to be placed to support the landing, extending floor up to same. Enclose the spandril of stairs with ⅞ in. sheeting nailed to side of string and to 2 in. x 4 in. floor clete, and to have ⅞ in. ogee moulded hose with shoe strip same as to balustrading, and to have moulded capping same as to wainscotting all complete. Stair newels to be of oak 8 in. square and turned, with turned mitre cap to same. The basement stairs to be constructed, as shown per drawings and as described for main stairs, with sheeted balustrading and newel posts in same manner all complete. Provide and construct steps to front and rear entrances, as shown per drawings, to have 2½ strings and 4 in. carriage pieces, 1¼ in. oak risers and 2 in. x 2 in. slatted treads of oak laid with ¾ in. space between, and well spiked and screwed down, the nails and screws to be counter sunk 3-16 of an inch. The platforms to front steps to be constructed with oak slats in same manner and to have 8 in. x 2 in. bearers under same built into main and parapet walls. Build oak coping to parapets of front steps with 2½ in. x 12 in. oak plank, chamfered on edges and spiked to 2 in. pine plank bolted down to brick parapet with ⅛ in. bolts, as called for in bricklayer's specification, and plank on 3 in. moulding of oak under oak coping. Platform to rear entrance steps to be built of 2 in. x 2 in. oak plank, grooved and tongued together, resting on bond timber built into main wall and at outer end on 6 in. x 8 in. timber built into parapet walls of entrance steps, to be neatly dressed and rounded on the nosing, and to have a fall outwards of one inch. The rear entrance steps up to ground floor level and down into basement will be constructed in same manner as described for front entrance steps. The coping will consist of 9 in. x 3 in. stuff chamfered on edges and bolted down to parapet walls as provided in bricklayer's specifications, the bolt nuts to be counter sunk and a 2½ in. round oak roll planted on top of same as shown per marginal diagrams. The walls at side of basement area steps to have pine coping 14 in. x 3 in. dressed on top and face and chamfered on edge, and to be coal tarred on the under side and outer edge and bolted down by ¾ in. anchor bolts provided and built in by bricklayer. Provide and construct "roof over rear and basement entrance steps, to have 6 in. x 6 in. dressed and chamfered posts tenoned into and spiked to parapet coping and to have 6 in. x 6 in. plates and cross bearers, and covered with ⅞ in. x 4 in. grooved and toqued sheeting laid double on 6 in. x 2 in. dressed rafters with ⅞ in. facia and crown moulding and fillet on sides and bottom. The posts are to be braced with 6 in. x 4 in. chamfered braces as shown per elevations, etc. The basement entrance to be covered with double ⅞ in. x 4 in. stuff resting on parapet coping and wall clete and battened on top with 2 in. x ¼ in. moulded battens, the upper steps roof to be battened in same manner. All the stuff for above mentioned roof to be of good, sound, clean and well seasoned pine, and all left in good order for the painter, complete in all respects. Provide and fix wainscotting to all closet rooms and corridors (except in basement), to be 3 in. x 6 in. in height with moulded capping and ⅞ in. x 8 in. moulded plinth and 1¾ in. moulded shoe strip, the wainscotting to be composed of alternate 2½ and 4 in. x ⅞ grooved and tongued and jointed sheeting of clear, seasoned, kiln-dried stuff, put together and blind nailed in most substantial manner. Provide and fix openings for exhaust ventilators in the base of wainscotting under all windows in class rooms, and two extra, making six in each class room, and provide and fix screens of galv. wire cloth to same with neat moulded frame around each, and provide and connect same down to the span formed by the counter ceiling. Provide and fix ⅛ in. jamb lining and soffit to all windows except in basement, also 1⅛ in. stools finished same level and forming part of wainscotting capping, the lining to be tongued into frames, and provided with ⅞ x 12 in. ventilating boards cut in between and held by neat moulded cletes. Provide and fix 6 in. x 1⅛ in. well seasoned and kiln-dried clear pine architraves to all windows and doors except in basement, all nailed to ⅞ in. x 3 in. grounds, well nailed to wall strips, etc., in walls. Provide and lay ⅞ in. x 10 in. thickness, sound and seasoned common flooring, ground and first floor throughout all well nailed down to every joist with two 3 in. nails, and after all plastering and trimmings are on and the building cleaned up, lay down best quality of ⅞ in. x 3 in. thoroughly kiln-dried white maple flooring, grooved and tongued and blind nailed and finished up smooth and close jointed throughout, and have the same clean and in thorough order for oiling. Put 1⅛ oak nosing boards to all well holes and properly fit and scribe to all walls and other parts. The carpenter will lock up each room as the floors are laid and until the painter is ready to oil the floors. Construct teacher's platforms at end of each class room, as shown to be 6½ high laid on 6 in. x 2 in. bearers, 18 in. centres, and floored with ⅞ in. x 3 in. maple flooring with 1⅛ in. nosing to same, and ⅞ in. pine riser rounded and moulded complete. Provide and fit up privy closets in basement as shown per basement plans and details. The floor to be laid with 6 in. x 2 in. bearers laid upon the finished cement floor, 18 in. centres, and floored with ⅞ in. x 3 in. maple flooring, same as other floors and with 1⅛ in. nosing to same. The seats to have ⅞ x 4 in. grooved and tongued sheeting for risers well nailed to trimmer bearer, and to have 1¼ quarter round planted in angle next to floor, and 1¼ in. x 3 in. clete along the top under seat. The seats to be made out of 1¼ in. stuff, with rounded nosing and perforated with graduated seat holes, 6 in. x 9 in. to 7 in. x 11 in. as shall be directed. Enclose the closets with 1¼ in. x 4 in. grooved and tongued matched sheeting 6 ft. 6 in. high with 2 in. x 3 in. capping chamfered on edges and ploughed to receive the ends of sheeting, also floor cletes in same manner. The doors to have 3 in. x 3 in. chamfered posts, rebated for 1¾ doors but without doors. Provide and fit up screen along the front of each range of closets and urinal as shown per plans and as described for privy enclosure, and in both cases extend the posts up to the ceiling and well spike and tenon the same into a 2 in. x 3 in. ceiling clete planted on to receive the same. The seats are to have 1¼ flaps or covers to the holes with 2 in. x 1½ cletes tenoned on to same and to be hinged with 6 in. wrot. T hinges put on with screws. Provide and fix 1¼ in. x 15 in. dressed board at back of urinal. Provide and fix grounds, boards and casing to plumber's piping, and all cutting and notching for same in the best and most substantial manner and as shall be directed. All woodwork for the above closets and screens to be of best seasoned stuff. The carpenter will provide and set all centres for bricklayer and provide and stay all frames and case in all cut stone work when necessary and as may be decided by the architect. The carpenter will attend on other trades and as may be necessary for the proper carrying out of the works. The core of the building will rest with the carpenter who will provide all necessary temporary doors and fastners to same, and will provide keys for the other trades to gain access to the building at all proper working hours, and will see that the building is properly closed in at nights and during Sundays. Provide and fix 1¼ in. iron hand rail at each side of main stairs made of 1¼ in. gaspiping secured to the side of stairway with wrot. iron brackets and finished to newels with iron socket flanges screwed on. These iron rails to be the same as those in Given St. and Ryerson schools. Provide and fix black japanned metal clothes hooks in each class room, screwed with four ¾ in. screws to the wainscotting and to be per sample in our office. There will be sixty of these hooks in each class room and 12 in teacher's room at end of corridor, and eight elsewhere directed by the architect, making 500 in all. Provide and fit up in each class room, and where recess in walls will be left for same, small cupboards 30 in. wide x 36 in. high and 9 in. deep, to have 1¼ in. side and front and 1⅛ in. flock panelled doors in two boxes hinged with 3 in. butts and fastened with good cupboard lock and to have metal knobs 2⅜ in. moulded stool and moulded cornice, and to project about 4 in. from face of plaster work on walls. These cupboards will have three ¾ in. shelves to same on neat moulded clete.

(To be Continued in March Number.)

BILL OF QUANTITIES.

EXCAVATION AND DRAINAGE.

	$	c.
1340 cubic yards of excavation, includes filling and ramming, etc., complete		
Cutting and grading around the building, complete		
Cutting, filling and grading the lot to uniform grade throughout, and carting away surplus earth		
Provide 9 in. sewer connection from street sewer to street line, at per lineal yard, complete		
Provide 9 in. continuation drain from sewer connections to point shown on plan, at per lineal yard		
58 lineal yards of 6 in. vitrified tile drains, includes Y's, bends, elbows, junctions and traps, etc., complete		
102 lineal yards of 4 in. vitrified tile drains, includes Y's, bends, elbows, junctions and traps, etc , complete		
80⅔ lineal yards of 3 in. x 4 in. weeping drain, includes packing with broken brick and coarse gravel, complete		

NOTE.—Excavations are measured "cube," that is, length, breadth and depth, thus: 54 ft. 9 in. x 22 ft. 6 in. x 5 ft. 6 in., equal to 6775 ft. 4 in., divided by 27, the number of feet in a cubic yard, gives 251 cubic yards, less 11 ft. 8 in). Tile drains are measured lineal, that is, running measure, as indicated in above items.

MASONRY.

93¼ toise masonry (86 ft. cube English measure) in foundation walls, pointed in cement mortar outside, complete		
2 toise masonry in vent, foundation, (Dimension stone)		
995 supl. ft. of Credit Valley stone, random coursed work above surface, inch draft and hammered dressed reveals; pointed in cement, complete		

NOTE.—Masonry is measured cube, and the totals of dimensions added together, divided by 86, the number of cubic feet in a toise. The French measure per toise being 6 ft. x 6 ft. x 2 ft., equivalent to 6 ft. 4½ in. x 6 ft. 4½ in. x 2 ft. 1½ in. English measure, the French foot being ¾ of an inch longer than one foot English.

PERSONAL.

In the CANADIAN ARCHITECT AND BUILDER for January the statement was made that Mr. Geo. Gouinlock, architect, Toronto, had entered into partnership with Mr. Garland. We regret that this statement was made without authority and under a misapprehension as to the facts. It has since been learned that the arrangement Mr. Garland had with Mr. Gouinlock, was only a temporary one, and that it has since been dissolved.

News has been received of the death at Hanford, Cal., of Mr. Jas. R. Bowes, architect, late of Ottawa, Ont. Mr. Bowes death resulted from injuries sustained by jumping from the second story window of a burning hotel.

Mr. Wm. Gregg, Jr., representing the Toronto Radiator Mfg. Co., at Winnipeg, Man., paid a visit to Ontario last month. He reports the building outlook for Winnipeg and the Northwest to be encouraging, and business in his particular line extending.

PUBLICATIONS.

Sir Edwin Arnold, who has been enjoying an interesting trip through the United States, has made a careful study of the conditions which govern the family in Japan and embodies his ideas in a paper called "Love and Marriage in Japan" in the February number of *The Cosmopolitan*. The article is illustrated by the quaintest possible Japanese sketches running down the sides and across the bottom of each page.

We have been favored by the publisher with a copy of a practical treatise by Mr. Owen B. Maginnis on the practice of centering arches in building construction in the United States. The book contains 65 illustrations, is well bound in cloth, and is sold at the price of $1.50. Wm. T. Comstock, New York, is the publisher.

TORONTO ARCHITECTURAL

CANADIAN ARCHITECT AND BUILDER.

VOL. V.—No. III. TORONTO AND MONTREAL, CANADA, MARCH, 1892. { PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),

PUBLISHED ON THE THIRD SATURDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

14 King Street West, - TORONTO, CANADA.

64 TEMPLE BUILDING, MONTREAL.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1892.

PRESIDENT	S. G. CURRY, Toronto.
1ST VICE-PRESIDENT	KING ARNOLD, Ottawa.
2ND VICE-PRESIDENT	F. J. RASTRICK, Hamilton.
TREASURER	D. B. DICK, Toronto.

COUNCIL:

WM. G. STORM	Toronto.
DAVID EWART	Ottawa.
S. H. TOWNSEND	Toronto.
JOHN E. BELCHER	Peterborough.
EDMUND BURKE	Toronto.

REGISTRAR AND LIBRARIAN:

W. A. LANGTON - Merchants' Bank Building, Toronto.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1892.

PRESIDENT	F. X. BERLINQUET, Quebec.
1ST VICE-PRESIDENT	VICTOR ROY, Montreal.
2ND VICE-PRESIDENT	J. NELSON, A.R.C.A.
SECRETARY	C. CLIFT, Montreal.
TREASURER	W. E. DORAN, Montreal.

COUNCIL:

A. T. TAYLOR, F.R.I.B.A., R.C.A.	Montreal.
A. C. HUTCHISON, R.C.A.	Montreal.
M. PERRAULT	Montreal.
A. F. DUNLOP, R.C.A.	Montreal.
ALPH. RAZA	Montreal.
J. F. PEACHY	Quebec.

SEVERAL of the largest manufacturers of lime in Toronto, Milton and Guelph have consolidated their interests, and will hereafter be known as the Ontario Lime Association. Toronto will be the headquarters of the Association. An effort will no doubt be made to stiffen prices.

THE Association of Provincial Land Surveyors of Ontario are applying to the Legislature for incorporation. For some reason or other the Bill which has been introduced with this object has met with considerable opposition. The influence of this opposition seems likely to also stand in the way of the required amendments to the Ontario Architects' Act.

A CORRESPONDENT writes: "Allow me to congratulate you on the editorial article on cement testing in February issue of CANADIAN ARCHITECT AND BUILDER. I for one would be very glad to see your ideas regarding the establishing of a Government laboratory for testing cements carried out. Should occasion require it, you are at liberty to use my name as having been one of the sufferers. I can fully corroborate the statements contained in your article."

COL. Tracy, City Engineer of Vancouver, B. C., advises us that it is the purpose of the council of that city during the approaching summer to commence the use of bituminous rock pavement. This material, which will be imported from Southern California, is described as being a good deal like asphalt, with the exception of being elastic, giving a good foothold to horses. Our informant regards it as being almost an ideal pavement. The success of this material will be watched with interest by other cities.

A CORRESPONDENT writes from British Columbia concerning Christ Church Cathedral competition, Victoria, B.C., as follows: "All designs received at this end are being forwarded unopened to the Church House, Westminster, Eng., where those prepared by English architects will be received. They will then be examined by Canon Beaulands and Mr. B. Ferry, architect, and the ten most suitable designs will be submitted to Sir A. W. Blomfield, whose decision as to the merit and award of prizes will be accepted by the plans committee. Some local architects have competed, but we believe many others have held aloof, not altogether liking the conditions of competition."

BUILDING operations in Montreal promise to be somewhat extensive during the approaching summer. Strong efforts have been made for a year past by certain real estate speculators to boom suburban properties, and in spite of the experience of Toronto, the older and more conservative city has shown itself to be susceptible to the boomster's art. It is unlikely, however, that speculation in land or building will be carried to anything like the pitch attained in Toronto during the recent period of inflation. While anything bearing the least resemblance to wild-cat speculation ought to be severely discouraged, every possible encouragement should be afforded to legitimate building enterprises.

THE Ontario Association of Architects will hold the first examinations under the Act of Incorporation at the School of Practical Science, Toronto, on the 5th, 6th, 7th and 8th of next month. Three examinations will be held at the same time, the first and second intermediates and the final, and there are some sixty candidates coming forward to undergo the tests of their proficiency in the various stages. The Board of Examiners consists of seven members: Prof. Galbraith, chairman, and Messrs. C. H. C. Wright, E. Burke, R. W. Gambier-Bousfield, S. G. Curry, F. Darling and S. H. Townsend. This is the first of a long series of examinations, let us hope the result of which will be that the danger the public are now in, of falling into the hands of unskilled practitioners, will in time be done away with. Now a youth must perforce go through a regular course of training, passing examinations at certain stages to test his progress and show him in what particulars he is weak, until having passed the final examination, he may practise his profession with honor to himself and for the good of the public.

THE architectural students of Ontario are at present on the anxious seat in view of the approaching April examinations. Many architects now in practice regret that such examinations were not required of them during their studentship. Students of the present day should, therefore, appreciate the facilities which, under the Ontario Architects' Act, have been placed at their disposal for acquiring a proper knowledge of architecture. With the object of assisting students who shall present themselves as candidates for examination, we publish a paper on "Heating and Ventilation," by the President of the O.A.A., Mr. S. G. Curry, and also a paper on "Elements of Building Construction" and "Structural Iron Work," by Mr. E. Burke, recently read before the members of the Toronto Architectural Sketch Club. The authors have been appointed examiners in the subjects treated of in their respective papers.

IT is every day becoming more apparent that the activity which was expected to mark the coming season in Toronto in consequence of the changing of the street railway system and the construction of permanent pavements on the leading streets, will not be witnessed. The Council are in a fair way to spend the balance of the year in discussing the merits of the trolley versus the storage battery system of street car propulsion, notwithstanding that their experts reported in favor of the trolley, and in the face of the fact that the experimenting which has been done by American cities points to the trolley system as being at present the only one which can be depended on to do the work satisfactorily, especially where heavy grades and heavily laden cars are among the difficulties to be encountered. It is right enough that the Council should endeavor to make provision for the adoption of a system more perfect than the trolley, should such be made available before the period of the present company's franchise shall have expired, but they are not justified in throwing over the carrying out of this great improvement for another year when the evidence all tends to show that no corresponding advantage is likely to be gained. The outlook for the building trades is none too encouraging. There is consequently the greater reason why the City should endeavor to afford employment on as extended a scale as possible to artisans and laborers.

THIS is not the first time that we have taken occasion to speak of the Mechanics' Lien Law and its many disadvantages. The act remains in force, and as long as this is the case there will be heard from all sides complaints of its cumbersomeness, expense in procedure, and its incomprehensiveness. We have more than once heard it said by "persons in authority" when asked to explain some part of the Lien Law, "It's not surprising you don't understand it, for nobody ever did." This assertion is, of course, an exaggeration, but it has a great deal of truth in it. Surely then it is time to amend a law that has such obvious flaws in it. Many people, and among them lawyers of eminence, contend that it would be better to abolish it at once. The fact is, the system on which the law is based is wrong. It encourages fraud, as it attempts to legislate for credit, giving considerable opportunity for dishonesty. It fosters speculative building, and dishonest builders have not failed to take advantage of it, causing an amount of distress, annoyance and embarassment that it would fill volumes to dilate upon. Were there no Lien Law, there would not be much credit. But under the existing state of things the material man prefers to sell his goods on credit and run the chances of being able to protect himself by a lien, to not selling anything, the man who gives credit being the one who secures the orders. The material man can come down on the innocent owner, and so can the workman, and force him to pay again that which he has already paid the builder who has abscooded, for the percentage retained in making advances to the builder rarely are sufficient to cover the whole costs. The system of credit is bad, but this plan of safeguarding the man who gives credit in order to sell his material is worse.

MUCH has been heard of the danger attendaot upon the system of stringing electric wires overhead, and reiterated demands have been made that all wires be placed underground. It is questionable, however, whether the carrying out of this demand would not tend to enhance rather than diminish the danger. An example of the peril which is likely to attend the underground system occurred in Toronto a few days ago. Illuminating gas from the street mains found its way in sufficient quantity into one of the man-holes in the public streets through which passes a telephone cable, to require but the faintest induction spark from the covering of the cable, or a spark of atmospheric electricity to cause an explosion. The spark appears to have been forthcoming; for suddenly the heavy iron man-hole covering which had been firmly bolted down, was torn from its seat and carried into the air. A horse which was being driven past the spot at the moment fell into the man-hole, and before it could be extricated there occurred a second explosion, burning the animal severely. The driver of the horse and another person who happened to be near the man-hole when the explosion occurred escaped with slight injuries. It is a well-known fact that about 10 per cent. of the total supply of illuminating gas which goes into the street mains leaks out at the joints and saturates the earth. This gas must find its way into the man-holes, and when the right admixture of gas and air is reached, the material is ready for an explosion. There is always danger with underground wires that the inductive current set up in the lead covering of the cable may become sufficiently strong to generate a spark which would be the means of igniting the combustible materials. Had the explosion to which we have referred taken place in the man-hole at the intersection of King and Yonge streets, where the traffic is always great during business hours, there would in all probability have been many persons killed. The daily press which has so often held up to view the horrors of the overhead system, should now have something to say on the other side of the question.

A VERY singular case has been before the courts for some time, and it will be probably many months before we hear the end of it. As it contains points of considerable interest, we give the story as far as it has gone at present. Three prominent men of Waterford, Ontario, built a block of business premises on the main street of that town. The boundaries of the street had not been definitely decided, but when they were, it was found that the new block encroached some six feet upon the street. The owners of the building were proceeded against for allowing a nuisance and were fined. They appealed, but the result was an order to remove the "nuisance" within three months. This they failed to do, and the County judge allowed a writ of *de nocumento amovendo* to issue, which enjoined the sheriff to pull down the projecting part of the block at the owners' cost. The barrister in charge of the owners' interests held that the County judge had not the power to issue this curious writ, but that it was a matter for the High Court. He succeeded in obtaining a writ of *certiorari* during the recent term, so that proceedings were stayed on account of the irregularity, and will proceed during the ensuing term to apply for a rule *nisi* whereby the present proceedings will be quashed. The case gains interest from the fact that the writ of *de nocumento amovendo* is said to be the first that has been issued for a hundred years. The matter may still be brought before the High Court, and if so, the owners are liable to a fine of almost any amount, and repeated fines until the "nuisance" complained of is removed. There seems to be a difference as to the term which may be applied to an encroachment upon adjoining property, for there is a case recorded in which, by a mistake, a house was erected with one side wall, just its thickness, nine inches, on the adjoining lot. In this case the owner was proceeded against, not for a "nuisance," but simply for encroachment, and when the sheriff was ordered to tear down the wall he found he could not do so without injury to that part of the house touching the wall on the other side, and clearly within the lot of the house owner. He had no right to enter upon the lot or touch anything therein, and so far as we have been able to discover, the matter had to be left in this state.

OUR ILLUSTRATIONS.

HOUSE FOR A. R. REID, ESQ., MONTREAL.—ALEX. C. HUTCHISON, ARCHITECT.

This building was erected in Upper Drummond street some eighteen months ago. The fronts are of red Scotch and red New Brunswick sand stone. It is at present without the library shown on the plan, but it is proposed to make this addition during this year.

CHURCH OF THE MESSIAH, AVENUE ROAD, TORONTO.—GORDON & HELLIWELL, ARCHITECTS, TORONTO.

SKETCH OF SUMMER RESIDENCE ON TORONTO ISLAND.—LANGLEY & BURKE, ARCHITECTS, TORONTO.

INTERIOR OF HALL, F. D. MONK'S RESIDENCE, MONTREAL.—J. W. & E. C. HOPKINS, ARCHITECTS, MONTREAL.

OBITUARY.

It becomes our painful duty to chronicle the death of Mr. John Webb, one of the oldest, most prominent, and most highly esteemed contractors of the City of Hamilton. Death was the result of a severe attack of rheumatism, culminating in severe spasms of the heart after an illness of seven weeks. The subject of this notice was born near Hythe, in Kent County, England. He came to this country in 1871, and immediately entered into business in Hamilton as a contractor and builder. Among the buildings erected by him may be mentioned the *Times* building, Ryerson school, West Avenue school, Canada screw works, James McPherson & Co's building, the buildings occupied by Messrs. F. W. Fearman & Son, Thos. Lawry & Son, W. H. Gillard & Co., St. John's Church, the Tuckett tobacco factory, and others which were both a credit to him and to the city. He leaves a widow and nine children, four sons and five daughters. Deceased was a member of Doric Lodge, A. F. & A. M., and a charter member of Gore Lodge, A. O. U. W. For a number of years he was an active member of the Charitable Committee of St. George's Society. He was noted for his uprightness of character and kindliness of disposition.

PUBLICATIONS.

Messrs. H. R. Ives & Co., have issued an attractively printed little book, embellished with a number of humorous illustrations, calling attention to the advantages of their Buffalo hot water boiler, corrugated soil pipe, etc.

Elizabeth Bisland opens the March number of the *Cosmopolitan* with an article on the Cologne Cathedral, beautifully illustrated from photographs. M. H. de Young, Commissioner of the World Fair from California, has a most interesting article on expositions. The illustrations accompanying this article are from the pen of Harry Fenn and adequately display to the readers the architectural glories of the Fair buildings.

CANADIAN CITY ENGINEERS.

V.

HURD Peters, City Engineer of Saint John, New Brunswick, was born at Fredericton, N. B., being one of the younger sons of Hon. Charles Jeffrey Peters, Attorney-General of that Province.

After passing through the Collegiate school (silver medal) Mr. Peters took his degree of A.B. and A.M. at King's College, from the University of N.B. (gold medal). He also took his diploma at the special course in engineering at that time instituted under Mr. Cregan, C.E.

After having been employed on the European and North American R. R. between St. John and Vanceboro and on what is now the Intercolonial, between St. John and Moncton, as leveller, he spent some time working in the United States.

In 1854, in partnership with I. Edward Boyd, M.I.C.E., who recently died while in charge of the harbor works, Quebec, he opened an office under the title of Peters & Boyd for private practice in St. John. When Mr. Boyd subsequently took a position on the government railways, Mr. Peters continued in private practice until April, 1861, when he was appointed City Surveyor. Two years later, July, 1863, he was appointed City Engineer—that office being then for the first time established—and has so continued to the present time. He was one of the first Council of the Canadian Society of Civil Engineers, and his name appears in the Act of Incorporation.

The record of Mr. Peters' work is to be found in the present state of the city, for which he has been engineer for some 30 years.

Mr. Peters has also taken an active part in militia affairs, having retired with the rank of Lieut.-Col. 2nd Battalion St. John County Militia. He has likewise filled positions of trust in connection with the Episcopal Church.

Mr. Peters had his residence and office with all his plans and memoranda, destroyed in the conflagration which overtook St. John in 1877.

MR. HURD PETERS, CITY ENGINEER, ST. JOHN, N. B.

QUERIES AND ANSWERS.

"J. B. R." writes as follows from the Northwest Territory: "It was the intention of the company with which I am employed as superintendent of construction to build concrete, but for different reasons the company changed to frame and rough-cast. This left a large quantity of Selkirk lime on hand. Last fall I dug a large pit 14' x 12' x 2', and ran it full. After covering it with a good layer of sifted sand, I placed a rough floor over this, then another layer of sand and protected this again with manure. Will I meet with as good results when I require it as if I had left it to air slake? I was never placed in this position before, but was once told by a stone mason that the longer the lime lay in this state the better."

[ANS.—Storing lime in the manner mentioned by our correspondent is calculated to improve rather than to injure the quality. In England lime is frequently stored in cellars for the purpose of improving it. When thus treated it is called "putty lime," and is chiefly used for finishing. Unless the lime has suffered from the severe frosts, it will no doubt be found all right, and we would advise our correspondent if possible to keep it for finishing purposes. It will be found to be cool and will not crack.—ED. C. A. & B.]

PROVINCIAL LAND SURVEYORS.

THE seventh annual meeting of the Association of Provincial Land Surveyor of Ontario, was held in the Canadian Institute, Toronto, on Feb. 23rd, 24th and 25th. In addition to the transaction of much important business, papers were read as follows: "Cement and Cement Mortars," Mr. J. Butler, P.L.S., C.E., Napanee, Ont; "Does the Passing of an Act of Parliament Alway do Justice?" A. Niven, P.L.S., Haliburton; "Hints to a Surveyor About to Survey a Township for the Ontario Government," W. R. Burke, P.L.S., Ingersoll, Ont.; "Compass Lines," John McAree, D.T.S., Toronto; "The Value of Old Records in Relation to Municipal Surveys," Geo. B. Kirkpatrick, P.L.S., Crown Lands Dept., Toronto; "Sewerage for Towns and Villages," H. J. Bowman, P.L.S., C.E., Berlin, Ont.; "Georgetown Water Works," James Warren, P.L.S., C.E., Kincardine, Ont.; "Hamilton and Barton Incline Railway," J. W. Tyrrell, P.L.S., C.E., Hamilton, Ont.; "Storage of Water on the Trent System," R. B. Regers, P.L.S., C.E., Peterboro', Ont.; "Exploring for Nickel," C. E. Fitton, P.L.S., Orillia; "Railway Surveys," H. K. Wicksteed, P.L.S., C.E., Cobourg, Ont.; "Rock Blasting of Trenches for Water Works and Sewerage Purposes," A. L. McCulloch, P.L.S., C.E., Galt, Ont.

On the evening of the 24th inst., a pleasant time was spent by the members at the annual dinner of the Association, which took place at the Arlington.

AMATEUR DECORATING.

By W. H. ELLIOTT.

I NOTICED a paragraph a short time since in a daily newspaper in which the writer bewailed the slavery into which suffering humanity had fallen to the autocratic decorator. "People," said he, "no longer embody in their rooms their own taste, and are denied the opportunity for displaying to admiring friends their admirable traits of character; on the contrary, a woman of simple tastes is put into a georgeous boudoir of extreme French design and so on." The perpetual hunting for a grievance in writing on aesthetic matters is at times very wearisome, especially in view of the fact that in most cases the fault-finding with existing conditions is not borne out by actual experience. The cry for something different continually goes up, though Heaven only knows what different is wanted. If French ideas are introduced the good old English simplicity has gone for ever. If solid English design is used the aesthetic grumbler sighs for the lightness and greater artistic beauty of the French. And now we are told that the helpless public has fallen hopelessly into the hands of the professional decorator, and what an unfortunate thing it is that one cannot choose one's surroundings for one's self, as if we do not all know that for a decade past the decorating amateur has revelled in a reign of terra cotta and muddy green to his heart's content, producing the most thrilling effects for those who responsively thrill. And it is only that we have emerged at last from this period of indefiniteness and taken up something requiring knowledge, skill and caution in its handling—I say it is only for this reason that our aesthetic Israelites are lamenting their captivity and the end of their muddy period. Now it is not true that the decorator usually serves all people alike without regard to their characters, tastes and positions. In a great many cases he has a clearer idea of what will suit his client than the client can possibly have because of his inexperience and lack of knowledge of many possible variations in the treatment of his rooms. In how many cases does the ambitious householder see an effect in somebody else's house or at an hotel or in a pullman car which if not modified or tabooed entirely by the decorator, would be appropriated for the house and lay the householder open to the ridicule of every one of good taste. We feel a tender pity for the man who commits himself to the "every man his own architect" sort of influence, but the results consequent upon every man becoming his own decorator are quite as sorry and frequently more palpable because of the lack of examples to follow, such as every builder of houses has in the houses already built.

The refined and classical styles at present in vogue calling for decorative taste of the highest order, cannot be successfully played with by ambitious amateurs, and yet may be safely used in some one or other of their variations to suit almost anybody's taste and pocket book. What more can we ask than that, after providing a suitable background, he leave to our individual tastes the many little accessories, that more than the walls and ceiling may be made to exhibit an individuality and preference. Prettier rooms by far will be made for the next few years than have been made in the preceding ones, and the effect will rarely be marred for the lack of interference on the part of the amateur decorator.

Messrs. Evans, Coleman & Evans have been appointed agents at Vancouver for the British Columbia Terra Cotta Co., of Victoria, B. C. The company have produced some fine samples.

A patent Spanish tile made of copper and tin is being manufactured by Merchant & Co., of Philadelphia. Among the advantages claimed for them is that they are much lighter and more durable than tiles made from clay.

The Manitoba Stone and Asphalt Paving Co. have started business in Winnipeg. It is their intention to engage in the manufacture of tiles, to construct asphalt pavements, and act as agents for American manufacturers of pressed brick, over-mantels, etc.

"ELEMENTS OF BUILDING CONSTRUCTION—STRUCTURAL IRON WORK."

THE following lecture to first and second intermediate students on the "Elements of Building Construction," and to second intermediate students on "Structural Iron Work," was delivered at the Toronto Architectural Sketch Club by Mr. E. Burke, examiner in the above subjects:—

In presenting a paper on the elements of building construction before the first year students, the brief time at my disposal will permit of but a rapid and cursory presentation of the subject. In fact, the most of your work is so admirably covered in Mitchell's "Elements of Building Construction" that I will avoid a repetition of the points there covered, and endeavor to touch some not mentioned—especially where Canadian methods differ from those in vogue in England.

Prof. Aitchison in one of his recent lectures said: "Building consists in putting the materials we have at command in certain positions, and giving them certain forms. The size and shape of these forms depend on certain statical considerations. Arithmetic, mathematics and geometery can alone enable us to solve the necessary statical problems; so these elements must first be mastered to enable us to solve the statical problems that present themselves. Next comes the knowledge of the strengths and capabilities of the materials we have to use." Fortunately we now live in times when these strengths and capabilities are being determined with more accuracy than in the past, although we have to admit that most of our data is so indefinite that we are compelled when we build to employ what is called a "factor of safety," which in reality is a "factor of ignorance." For instance, a beam of a certain scantling is supposed to break under a strain of a certain number of pounds. As a matter of fact it may break at half that amount, as was demonstrated at the School of Science during our late convention. Hence it is usual in our constructions to allow from 5 to 10 times the supposed breaking strength of a material for a so called "factor of safety."

The first point in commencing a building is the question of the nature of the soil or bed upon which the walls are to rest. If this be of rock or of some compact dry substance which is comparatively unyielding, it is called a *natural* foundation and may be built upon directly. But if the ground is too soft to bear the weight of the structure required, it will need an artificial foundation. This may be obtained in a variety of ways: *First*, by planks in two or more thicknesses laid reversely and of sufficient breadth to sustain the weight above without undue settlement; *second*, by a bed of concrete of sufficient depth and width; *third*, by piles driven to a solid bottom, cut off evenly at tops to receive plank, concrete or stone footings; and *fourth*, by a gridiron of steel rails as developed by the necessities of Chicago building operations, where great spread is required in proportion to the height available for the footing courses. Where planks or piles are used, it is imperative that they be constantly submerged in water to prevent decay and the eventual collapse of the foundation of the structure. Footings should not project more than two-thirds of their thickness beyond the work above, and at least two-thirds of their width should be covered by the work above. Good rubble walling should be composed of stones thin in proportion to their length and breadth. The centre of gravity should be observed in placing the walls upon the footings and base of the building, allowance being also made for the weight of floors and partitions. In placing columns carrying weight it is of the utmost importance that they should be centrally placed. The non-observance of this rule was one of the causes of the accident to the Montreal Y.M.C.A.

The various bonds of brickwork used in England are clearly explained in "Mitchell." American bond, called "Stretching" or "Chimney Bond," is only recommended for ½ brick walls; while it makes a weak wall it certainly produces a much better appearance in a 9" wall than any other method of laying. A wall of this thickness having headers cannot be built smooth and even on both sides, as all bricks vary more or less in length. The diagonal bonders every 5th course give a wall built with this bond as much stiffness as is necessary for a wall of the limited height to which one this thickness should be carried. This bond also lends itself to the construction of hollow walls where one shell is but a half brick thick and can be bonded into the rest of the wall with hoop iron ties which should have a dip to prevent the water of condensation being carried to the inner thickness of the wall.

Mitchell speaks of built up wooden beams, that is, beams made up of several thicknesses of stuff, in connection with temporary structures chiefly, and that they are economical. In our practice this method of construction is considered superior to solid beams. Among others are the following reasons:—The material being of thin stuff, defects can be more readily detected and a superior quality secured. With several thicknesses the change or reversal of the grain thus obtained helps the stiffness of the construction, and by a system of splicing or breaking joint, no two joints coming opposite, long spans may be covered, such as the tie beams of roof principals. And lastly, the wood may be obtained better seasoned.

Much of the splicing, cogging, jointing and morticing dealt with in Mitchell is practically obsolete in this country, much better results being obtainable by the use of wro't iron bolts, straps and stirrups, the use of which avoids the inevitable weakening of parts which should be the strongest. The high rate of wages is also prohibitive, as the making of the joints illustrated would consume an immense amount of time, which in these days is, indeed, money. At the same time a great deal of the common class of work of to-day is to be deprecated,—there is too much tendency to "knock things together," superinduced by the craze for cheapness and inordinate haste, after the example set by our restless cousins to the South who use the almighty nail and trust it implicitly. With us deep joists are so readily obtainable that we do not need, as a rule, to resort to the English method of beams at comparatively short spacing and light joists with a counter ceiling to conceal the beams: a method wasteful as to height and creating in the large hollow spaces a very paradise for vermin. The practice of bevelling the ends of joists to prevent injury to the walls in case of fire is not mentioned, but is a very necessary precaution, perhaps more in regard to the prevention of loss of life and spread of fire than in the mere saving of the walls themselves. None of the methods of jointing flooring equal ours for adaptability, simplicity and ease of laying. Much of the ordinary work in England is without jointing, permitting dirt and moisture to drop to the ceiling or floor below.

In regard to roofs, the student must be warned against the examples in "Mitchell" where gutters are formed behind parapet walls. The only successful roof in our climate is that which permits the snow and ice to have free escape to the ground. To this end valleys should have ample space at the foot, enlarging as they approach the eaves, and gutters should invariably be set low enough to permit snow to slide off without obstruction. A bell-cast at the foot of the rafter will accomplish the same object. Facias should also project sufficiently to have a drip clear of the walls beneath.

Slates or tiles must, with us, be laid upon a solid substance. The English method of setting upon battens would permit our fine dry snow to blow in, and the extreme cold outside and the heat inside would cause condensation on the under-side resulting in wet ceilings. The roof principals illustrated, are entirely of the low pitch type, but a mastery of the principles of their construction will enable the student to soon grapple the points of other forms. The method of constructing principals with wooden king and queen posts is now practically obsolete. The great number of joints results in considerable shrinkage unless constantly tightened up, resulting in sagged roofs and strained walls. Roofs of composite construction are now in general use, where at least the king or queen bolt succeed the posts of the same name.

The practice of battening walls for the sake of warmth and dryness is not mentioned and does not seem to be usual in English practice. It seems strange that in such a humid climate some more successful method than that of the hollow wall has not been introduced. The hollow wall does not thoroughly meet the necessities of the case, inasmuch as a certain proportion of the wall, as at piers, openings, &c., must be solid. The hollow wall has the advantage of permitting a more solid job of plastering and should be used in work likely to meet rough usage, but it cannot compare in dryness and comfort with the battened wall. The disadvantages of the latter are, however: 1st, the danger of conveying fire through several stories; and 2nd, the opportunity for the free passage of vermin. Both these contingencies however can be avoided by proper breaks or stops at all floors and ceilings, either by sailing courses of brick, or by horizontal battens at the ceiling and floor line.

Mitchell's chapter on joinery conveys practically all the information necessary in the ordinary experience of an architect's office, and a careful perusal is recommended.

The following is an outline of the work with which the 1st and 2nd intermediate students should be familiar in connection with the coming examinations on "The Elements of Building Construction:"

The various bonds in brickwork in ordinary use, offsets in footings, ganged arches of various forms and inverted arches, trimmer arches for fire-places, corbelling.

Sketches of mason work showing uncoursed and coursed rubble; ashlar and the proper bonding of the same; window sills, stone heads, strings, copings and quoins; methods of connecting stone by cramps, dowels and joggles.

Show how to scarf, mortice, tenon and build up timbers as applied to plates, roof timbers, beams and partitions.

Draw simple roof truss, king or queen post or rods, with details of framing and iron work.

Draw floor beams, joists, trimmers and coverings, or floors single and double: a framed partition with a door opening in it.

Draw a section of door and window frames, the latter boxed, casement or lead glazed; section and elevation of plain, panelled, moulded, raised panel and bolection moulded doors.

Show how to flash on a felt and gravel roof, and also the flashings of a sloping roof at parapet walls; also construction of gutters suitable for this climate.

In the Second Intermediate the student should also be able to draw sections of various forms of cast and wro't iron columns, the latter built with Z bars or angle iron; section of head and foot of superimposed columns showing method of connecting.

Explain the various strains to which iron is subjected in buildings.

Show section of wro't iron girders and connections of cross beams; proper method of anchoring beams to walls.

Show simple composite andiron ro of and other trusses, with details of connections.

"STRUCTURAL IRON WORK."

A Flitch girder is composed of two or more sticks of timber with a wro't iron plate inserted between the wood and bolted.

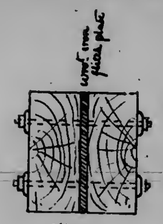

Fig 1

This form is now practically obsolete as the rolled iron or steel beams cost little if any more. Cast iron girders are also practically obsolete, being limited to very short spans in the form of lintels over door or window openings, and are unreliable owing to the possibility of hidden defects in castings, resulting in collapse in case of a sudden shock, or in case of fire, when they will crack on the first application of a stream of water. They should never therefore be trusted without a relieving arch above.

Fig 2

The sectional form of a cast iron girder should be different from that of one of rolled iron. The lower or tensional flange should be 4 to 6 times the area of the upper or compressional, as cast iron crushes with an average weight of 45 tons per square inch, and fails in tension with a pull of from 7 to 8 tons per square inch. Mitchell gives the depth of from 1-10th to 1-15th of the length, and the compressional flange 1-30th to 1-40th of the length. Wro't iron girders are much more reliable than cast, although they will yield by bending under a high temperature, such as is reached in a burning building. The difference in strength between compression and tension in wro't iron is so small that little or no attention need be paid as to the comparative dimensions of the upper and lower flanges, except in very heavy work. Wro't iron crushes with an average weight of 17 tons per square inch, and fails under a tension of 22 tons.

Fig 3

When one girder is not sufficient to carry the weight required, two of the required stiffness are placed side by side, and their relative positions retained by separators, which may be of cast iron with holes for the bolts to pass through, or they may be of short pieces of wro't iron pipe cut to the required length through which the bolts are passed. When girders over 12" to 15" deep are necessary, they are usually built up with rolled iron plates with angle iron connections or stiffeners. In the construction of columns, cast iron is the most largely used material, although rolled iron is being used more freely, especially in the construction of tall structures requiring the largest proportion of strength in comparison with space occupied. In these structures it is absolutely necessary that the material should be flawless and capable of resisting torsion and other strains which would snap cast iron and bring the structure to the ground. Columns of wro't iron will not resist heat as long as cast iron and consequently must be protected from the effects of fire when they have to carry important weights. The forms of wro't columns are numerous, the Z bar being the basis of those most used. Cast iron is so subject to flaws, often times hidden, that a large excess of material has to be provided in order to guard against failure.

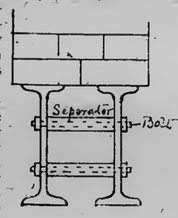

Fig 4

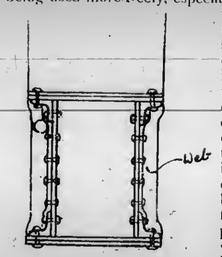

Fig 5

Fig 6

Fig 7

Fig 8

A column which may appear perfect on the surface may be little stronger than cardboard. One side may be 1½" thick and the other only ¼th, or what may appear to be only a slight ridge or depression may be a serious defect, called "cold shot" leaving the column practically open on one side.

No column may be pronounced safe unless it is drilled in several places in order to test the evenness of the thickness of the metal. Cast iron columns are of various forms, circular, however, being the strongest in proportion to the weight of metal used. Whenever possible, the webs or flanges should be reinforced with brackets or stiffeners at frequent intervals, and there should be no abrupt internal angles or transition in form. Castings should also vary in thickness very gradually. Cast iron should not bear upon cast iron when carrying any important weight without the bearings being turned or faced in order to remove any lumps or inequalities from their surface to give them an even bearing. Plates or caps should have a raised rim so that when the bearing is turned, the unfaced surfaces will still be removed from contact. Iron roof trusses are now composed entirely of wro't iron, except the foot, which is usually of cast iron. The following forms are outlines of typical trusses.

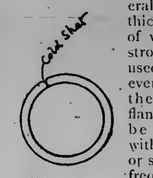

Fig 9

Fig 10

Fig 11

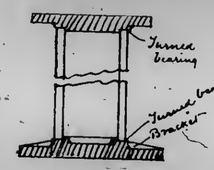

Fig 12

The joints are made with flat plates rivetted to the webs of members in compression and drilled for pins receiving ends of tension rods.

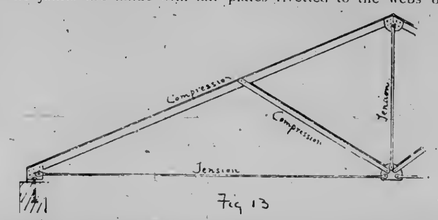

Fig 13

Trussed beams in ordinary practice are generally composite

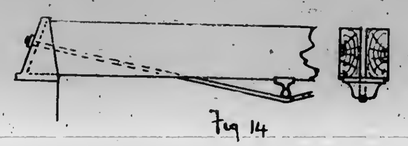

Fig 14

in structure, the ironwork being confined to cast iron shoes and wro't iron tension rods and the necessary bolts.

PERSONAL.

Messrs. Tripp & Wills, architects, have opened an office at New Westminster, B. C.

Mr. O. A. Graydon, city engineer of London, Ont., has been elected a member of the Canadian Society of Civil Engineers.

Messrs. R. C. J. Dunn and J. C. T. McKean, architects, St. John, N.B., have recently formed a partnership under the name of Dunn & McKean.

Mr. Joseph Hobson, chief engineer of the southern division of the G.T.R., has been appointed a member of the council of the Canadian Society of Civil Engineers.

Mr. John Miller, of the Pease Furnace Company, Toronto, formerly of London, has accepted a position with a large furnace firm in Chicago, and leaves for that city shortly.

The name of Mr. Geo. Gouinlock, of Toronto, was inadvertently omitted from the list published in our last issue of architects present at the annual convention of the O. A. A.

Mr. M. B. Aylesworth, Architect, Toronto, has just returned from a four months tour in Great Britain, the continent and the United States. He describes his trip as a most enjoyable one.

Mr. Geo. Theodore Bertheron, the oldest portrait painter in Canada, died in Toronto recently. He was born in Vienna, in 1806. He was the oldest member of the Ontario Society of Artists and was also an associate of the Royal Canadian Academy. He painted the portraits of many eminent Canadian jurists and parliamentarians.

The Standard Drain Pipe Co., of St. John, Que., are adding to their plant a 125 h. p. engine.

MR. JOHN KENNEDY, M. I. C. E., M. C. S. C. E.

JOHN KENNEDY, Chief Engineer of the Harbour Commissioners of Montreal, elected in January last as President of the Canadian Society of Civil Engineers, is a native Canadian, having been born at Spencerville, Ontario. He has for many years been a member of the Institution of Civil Engineers, England, and also of the American Society of Civil Engineers, as well as a charter member of the Canadian society.

Mr. Kennedy, in his long and active career in engineering, has had a variety and compass of experience that fall to the lot of but few in the profession—in fact, that can fall to the lot of those only who are gifted with rare powers.

A very brief and imperfect summary of the steps by which he has risen from a pupil in the office of Mr. Thos. C. Keefer, Past President of the Can. Soc. C. E., at the age of 15, to a foremost place in the highest rank of the profession, may be mentioned. His experience in municipal engineering was gained in the city of Montreal, where at an early age he was deputy city surveyor; in mining engineering, as manager of the Hull Iron Works; in railway engineering, when in four years he rose from being division engineer on the Wellington, Grey and Bruce Railway, to be chief engineer of the Great Western Railway, when at the summit of its activity and expansion; in the specialty of water works, in which he has been more or less intimately connected with nearly all the larger water works in the Dominion; in consultation or designing outright, as in the case of the pumping machinery of the Ottawa water works which, as an example of design would alone establish a reputation; in mechanical engineering in general, in which he is a recognized authority, having been widely consulted in various kinds of mill machinery, and in dredging machinery, his designs being found on the Pacific and the Atlantic, on the waters of Oregon, Charleston, New York and the St. Lawrence. In general hydraulic engineering he is also an authority, his advice having been sought by the Dominion and Provincial Governments and a wide range of municipal corporations and private companies. He has managed the deepening of the St. Lawrence ship channel, and still conducts the Montreal harbour works with marked ability. On arbitrations and commissions his experience and counsel are constantly in demand, as on the Trent Valley Canal Commission, the Lachine Canal Commission, the Commission on remeasurement of construction work on the Canadian Pacific Railway, the Montreal Flood Commission, and many others, and as an expert he has been frequently called before the committees of the Privy Council.

Mr. Kennedy's assistance has ever been freely and fully given to any professional brethren who have asked his advice. His ability as an engineer, his integrity as a man, and the extent of his reputation at home and abroad, give the assurance that in electing him President of their Society, the civil engineers of Canada not only honour themselves and him, but advance as well their own interests and standing as a professional body.

JOHN KENNEDY, ESQ., C. E., MONTREAL.

ORNAMENT IN ARCHITECTURE.

ORNAMENT is extremely useful in conferring on buildings a degree of elegance and richness which, without it, would be difficult to obtain; and it also may be made to convey an impression of wealth and magnificence which, in its absence, could only be attained by increased dimensions or massiveness, which would be as expensive and, in some instances, at least, less effective. Ornament is also extremely useful in altering the apparent proportion of buildings. Thus, by the employment of strongly marked horizontal lines, a building which is too tall may be reduced to proportion; one that is too low made to look nearly as high again by employing only vertical features. Buildings that from the inherent necessities of their construction look weak may be made to appear of any desired degree of strength, and sparkling gayety of effect be given to those that otherwise would be too massive and heavy. Internally the architect very often cannot control the dimensions of his apartments, but by a judicious application of ornament he may always make low rooms look higher, narrow rooms broader, and reduce long rooms to a better proportion. More than even this, ornament enables an architect to give to every part of his design exactly that degree of prominence and dignity, and that class of expression, which suits its position or purposes. These are all legitimate uses for the employment of ornament, and when used for these purposes it is never offensive. It always becomes so when it is employed to conceal either use or construction, or to make a building try and look like what it is not or cannot be.—*Scientific American.*

HEATING AND VENTILATION.

Mr. S. G. Curry, who has been appointed examiner in the above subjects in connection with the O. A. A examinations, recently addressed the members of the Toronto Architectural Sketch Club substantially as follows:

I propose to treat my subject in a very general way and not to go into detail to any extent; my object is to discuss heating, but as ventilation is largely bound up with heating it is impossible to treat of the one without the other.

The ordinary fire-place was the first method of heating adopted in our houses, and while it might not have been the most satisfactory method of warming a room, it answered most satisfactorily the purposes of ventilation. A fire-place warms a room by radiation, the heat rays passing through the air and warming the walls, floors, ceilings and any other articles which may be in the room and within range of the fire.

The next method was that of stoves, which warmed the rooms to a slight extent by radiation, but principally by convection or the heating of the air by passing over the heated surface of the stove.

Stoves gave place to furnaces placed in the basement, which heated large quantities of air to a high temperature, the air thus heated being conducted by means of pipes to the different rooms to be warmed.

The ordinary hot air furnace has developed, until we have different forms of hot air, steam and hot water combination furnaces, the object of the combination furnaces being to heat the central portion of the house near the furnace with hot air and the more distant parts with steam or hot water radiation.

Hot water heating is a favorite method. In this system water is heated in a boiler, placed in the basement and conveyed by means of pipes to radiators placed in the rooms to be heated. The heat which has been absorbed by the water is given off through the radiators placed in the rooms. Indirect heating by hot water is used to some extent: the air being brought in from the outside, warmed by passing through a heater placed in the basement and conveyed through the pipes to the rooms above.

Steam heating in its general principle is very similar to the hot water method, there being a boiler in the basement with radiators placed in the rooms to be heated, the steam being conducted from the boiler to the radiators and the water resulting from condensation being returned to the boiler through pipes. With steam, indirect heating can be used most satisfactorily.

It may be well to consider the advantages and disadvantages of the various means of heating our buildings. The fire-place is only of service in small rooms, and in this climate is altogether inadequate except in mild weather. The fire-place has these advantages: It heats entirely by radiation, and consequently does not raise the temperature of the room above a reasonable and healthful degree; it is also an effective means of ventilation, as all air required for the combustion of the fuel is withdrawn from the room, thus causing an inflow of fresh, pure air. Its principal disadvantage is, that owing to the fact that the fire-place warms a room by radiation a person sitting near the fire may have the portion of the body exposed to the fire extremely warm, while the rest of the body is proportionately cold. This effect is caused by the heat's rays striking the portion of the body exposed to the fire, while at the same time the temperature of the air in the room may be very low owing to the walls being cold. The air in the room can only be warmed by coming in contact with the surfaces of walls and furniture which have become warm through being within range of the fire and thus receiving heat by convection.

Some manufacturers and dealers have been selling low down grates, claiming that they warm a room better than a grate set high up. Such is a mistake, because when the fire is set low down near the floor, the heat rays cannot strike the floor except at an angle so obtuse that the floor derives very little heat from the fire. A high fire will throw the heat rays at a less obtuse angle, and will consequently warm the floor better. The heat rays from a low fire will pass over the floor in almost parallel lines. In countries where the fire-place has been depended upon for heat, many very ingenious grates have been invented with the object of warming the air in the rooms by passing it around the fire and discharging it back into the room, or for taking fresh air from the outside of the house and discharging it into the room after passing it around the back of the fire-place. Grates of this description have not come into use in this climate as they would not be able to warm the rooms properly, and consequently some other means of heating must be adopted which is generally sufficient without the assistance of the fire-place. We thus lose the benefits of the ventilation which always results from the use of a fire-place, even though it has no special arrangements for supplying fresh, warm air.

Very little can be said in favour of the method of heating by stoves, except that it is capable of economically heating rooms to a very high temperature. A stove heats a room slightly by radiation, but principally by convection, as already stated. The walls and floors remain comparatively cold as they receive no radiated heat, and the contact of the warm air does not warm them in any degree equal to that radiated from a fire. The reverse is the case—the walls through being colder chill the air of the room. There is a slight amount of ventilation caused by the withdrawal of the necessary amount of air to support combustion in the stove. Fresh air, as in the case of a fire-place, comes in through cracks and crevices in the windows, doors, etc. A great number of arrangements have been made whereby ventilation may be secured with the use of stoves. The stove pipe has been placed within a second pipe so that the heat from it would induce an outward current between the two pipes, thus ventilating the room. Casings have been constructed around stoves, so that the air to be warmed was made to pass up between the stove and the lining. This was first done with the object of drawing the cold air from the floor and warming it. After a time the casing was carried down to the floor with a number of holes near the base, through which the cold air might be drawn, and at the same time a pipe was put in which connected with the outside air. The fresh cold air entered through this pipe, and was discharged under or at one side of the stove in such manner that it was warmed between the stove and the casing. With slides covering the openings into the room at the bottom of casing and with the dampers in the pipe supplying fresh air, it was possible to regulate the temperature of the room to a nicety, for if the room got too warm, by closing the slides at the bottom of casing and opening the damper in the fresh air pipe the temperature could be lowered very rapidly, or if the room got too cold, by closing the dampers and opening the slides the temperature could be raised very quickly. Many modifications of the above arrangements were brought into use, and in the majority of cases were found to be satisfactory. Having adopted the casing around a stove, placed in the room to be warmed, it was but a short step to place a stove with this casing in the space adjoining the room to be warmed or below it. Thus by degrees the hot air furnace became a reality. An ordinary stove with casing was placed in the basement, and, as it was found to be satisfactory for the heating of one room, it gradually came into use for the purpose of heating a number of rooms. As a result, the small stove gave place to a larger one and the large stove to the furnace, which is really nothing more than a stove specially designed for the work which it has to do.

The principal benefits to be derived from the use of a hot air furnace are the doing away with a number of fires placed in stoves for one large fire, with a consequent reduction in attendance, and the bringing of fresh air into the house, which provision is always made in the erection of a furnace. If the furnace is of ample size and the fresh air opening left open, a house warmed by the means of a hot air furnace will be reasonably well ventilated. The air in a house heated by a hot air furnace may be very impure, not because the house is so heated, but because the apparatus is improperly managed or is defective. If the occupant objects to burning the necessary fuel, closes the fresh air inlets and draws the furnace supply of air from the house, he cannot expect very pure air. He is simply making his heating system correspond to a stove in his room without a supply of fresh air. The air of the house is carried through the furnace over and over again. When it becomes cold it drops to the floor and from the floor is carried through the furnace, where it is warmed and again discharged to the different rooms to be warmed.

The principal point to be observed in setting up a hot air furnace in a house is to put in a furnace of large size—the larger the better. A large furnace will be more economical than a small one; even an excessively large furnace will not burn any more fuel than a small one. If a small furnace is put in it will be possible to keep the house warm in mild weather by ordinary fires, but in cold weather the furnace will have to be driven beyond its capacity. This driving of the furnace means that it becomes over-heated and possibly red hot, and the air passing over it is heated to a temperature far too high. If air is heated much beyond 140° F., it is positively not in a proper condition for breathing. All its vitality has been abstracted, and it is so dry as to absorb moisture from any and every substance in the house, thus causing the woodwork to shrink to an extent which one would not think possible, besides abstracting moisture from the occupants of the house to their serious injury.

Having arranged to put in a large furnace, in what portion of the house should it be placed to give the greatest satisfaction? In this climate where the prevailing winds are from the north-west, the furnace should be placed towards that side of the house. If it is not so placed it will be found very difficult to get any warm air into the rooms which lie north-west of the furnace, the warm air going almost entirely to the rooms on the opposite side. The furnace should not be placed too far from the centre of the rooms to be warmed, as it is possible to go to the opposite extreme and find that the rooms to the south-west of the furnace cannot be heated, because the air has to be carried through too great a length of horizontal pipe. At times we have very cold east winds, which makes it difficult to warm rooms with an easterly exposure, and if the furnace is placed too far from these rooms it will be impossible to heat them under such conditions. A hot air furnace requires for its satisfactory working that there should be some means of withdrawing air from the house. In the ordinary house a very large amount of air escapes by means of cracks and crevices around windows and doors, about the base boards, and also to some extent through the walls. The best way to arrange for the discharge of impure air is by the means of a fire-place, which will withdraw the cold air from the floor, which is the proper point at which ventilation should be sought in a furnace heated house. Those fire-places which have flues in inside walls will nearly always be found to be withdrawing air from the room in which they are placed. A fire-place with a flue in the outside wall cannot be depended upon to withdraw air except a fire is burning therein. For a compactly built house of ordinary size, a hot air furnace is a very satisfactory means of warming, provided it is of ample size and there is a proper number of fire-places in the house. Of course it is to be understood that the furnace, hot air pipes, ducts, etc., have been put in by a man who thoroughly understands hot air heating.

The hot air furnace has been modified to some extent by the addition of hot water or steam heating in combination. This was first brought about by hot air furnaces being placed in houses having rooms so situated that it was impossible to heat them from the furnace. It occurred to some one that if a coil of pipe were placed within the fire pot of the furnace and connected to several radiators placed in those rooms which could not be heated by hot air, the difficulty would be solved. This arrangement was adopted in its crude form, but was not considered satisfactory by those who understood its drawbacks. The principal and most serious objection was that two openings had to be cut in the furnace which could not be closed tightly and which consequently allowed the gases of combustion to escape from the fire pot into the space surrounding the furnace and from that space into the house. It was also necessary to put on considerable amount of radiating surface, for if such was not done and the furnace was fired hard, trouble was almost sure to arise through the over-heating of the water in the coil and pipes. The idea was taken up, but instead of having a hot air furnace with combination hot water heating, a hot air and steam combination furnace resulted. This furnace was made of wrought iron with a steam generating chamber at the top of furnace. The air was warmed in the usual way by being passed over the outside surfaces of the furnace, and the steam was generated in the chamber above the furnace by passing the hot gases through vertical tubes as in a vertical steam boiler before allowing them to escape into the main flue. The central rooms were heated by hot air, and the rooms at a distance on the exposed sides of the house by radiators, which were supplied with steam from the chamber at the top of the furnace. This style of furnace is very satisfactory, provided it is properly put in and too much work is not expected of it. Lately a hot air and hot water combination boiler has been invented. It is really a hot water boiler, as it does nearly all the heating by means of hot water, the warm air being auxiliary to the hot water. The fresh air is made to pass around and over the boiler and is then allowed to escape into those portions of the house which are deemed to require plenty of fresh air. This form of boiler is not able to heat more air than is absolutely necessary to keep a house supplied with sufficient fresh air to maintain a reasonably healthy condition.

The next method of heating with which we will deal, is that of hot water as it has been practised for several years past. The boiler is placed in the basement, and flow and return pipes are run to radiators placed in the different rooms to be heated. The pressure on the system is that due to the head of water given by the height at which the expansion tank may be placed. The pressure at the tank, of course, will be that of the atmosphere. The pressure at the boiler may be 15 or 20 lbs., or even higher, in the case of a very high building. With this system it is practically impossible to get the water at any time much above 212 degrees, for if it should be heated higher than that it will change into steam at the expansion tank and blow off to the atmosphere, having its place taken by fresh cold water which will lower the atmosphere of that in the boiler and pipes very quickly. Some years ago nearly every radiator had its independent supply and return mains, or at the most there were not more than two or three radiators fed from the same main, and they were invariably placed at the same level, so that they would feed equally well. Of late years the tendency has been to place more radiators on

the same feed pipe and use great care in seeing that the connections were so made that each radiator would get an ample supply of heat. At the present time the tendency is to run mains for hot water heating very much on the same principle as steam mains are run. This method has been found satisfactory if the hot water engineer is thoroughly acquainted with his work and understands the principles governing hot water regulation. In the hands of an ignorant mechanic the results would be most disastrous. In very good and elaborate work the mains are valved so that it is possible to cut the heat off in any portion of the building without the least interference with the working of the balance. With hot water heating a steady uniform temperature can be maintained at all times with very little trouble. There is very little improvement in hot water heating over that derived from stoves, except that due to the fact that the air in the house is heated on a very large surface at lower temperature. It is the same air which is warmed over and over again, except whatever may come in through cracks and crevices owing to the difference in pressure between the cold outside air and the warm air in the house. As a rule nearly all the hot water heating has been done without any attempt at introducing fresh air.

Indirect hot water heating has been tried in this climate but with little success. The risk from frost is very great, and if the heater should become frozen the damage done is by no means light. It is possible during the day to have the benefit of indirect warming, when the fire can be kept burning brightly and there is some one to watch the heaters, dampers and fresh air supply, but to allow indirect heating to be continued during the night is exceedingly dangerous, because the outside temperature may drop very low and the fire under the boiler may become burnt out, in which case the heaters would freeze very quickly and cause a large amount of damage. I am aware that indirect hot water heating has been tried, and that according to the statement of those who have put it in, it has been found satisfactory. A careful examination of every so-called indirect hot water system will show that in nearly every case the air is supplied to the heater from the basement, and not from the outside, as soon as the weather becomes at all cold. In fact there are indirect hot water systems where the air is never taken from outside the house, but is brought from the basement at all times. It is possible by a very carefully arranged system with a very large boiler surface and great care on the part of the attendant, to pass a plentiful supply of fresh air over hot water pipes in the ordinary way, but the safest, most economical and satisfactory method is to build a brick enclosed space of such size as may be necessary, similar to that surrounding a hot air furnace. By placing a large quantity of pipe in deep coils, cold air may be warmed with a reasonable degree of safety. Fresh air should be brought in at the bottom of the space, with the opening so arranged that the incoming air cannot blow on to the hot water coils. Tin pipes are then taken from the sides of the enclosed space to the different rooms to be warmed. By arranging several of these warming chambers, according to the size of the house, a house may be fairly well warmed by the indirect system without much danger of damage from frost. There will have to be less or more direct heating surface in every room to be used in cold weather, as it will be found impossible to keep a house warm by the indirect hot air plan, as it is impossible to pass a large volume of very cold air through the heating coils. Hot water heating in an ordinary sized building will be found very satisfactory, but when the building is very large, steam heating will give better satisfaction.

The steam heating system is very similar to the hot water system in general outline. There is the boiler in the basement with supply and return mains to radiators placed where heat is required. A steam boiler may be of any size from a small portable one to a very large boiler similar to those used for generating steam for power purposes. In steam heating on the gravity principle there is but one large supply main and corresponding return back to the boiler. The steam is taken to the different radiators by means of branches from the main supply, and the water of condensation returned in like manner to the main return.

With a steam plant it is possible to have a first-class indirect heating job. The indirect heaters are generally placed in the the basement below the rooms which are to be warmed with a hot air flue running up to the rooms to be warmed. The fresh air may be supplied to the different indirect heaters by means of one or more common fresh air ducts, or an independent supply may be brought to each heater. The latter method, if it is possible, is the better to adopt, as each heater having its own supply will always have the necessary quantity of fresh air. With one common duct, if the system is not very carefully arranged, the heaters which supply air to the rooms on the upper floors will draw such large quantities of air as to practically rob the heaters to the ground floor. In bringing fresh air into the heaters it is necessary to arrange checks in such a way that cold currents of air can not be driven upon the radiators. The fresh air should rise slowly to the bottom of the heaters through an ample opening. Where the air is brought from the outside separately to each heater, it will be well to take it low down towards the floor and then allow it to ascend to the heating chamber. The supply and return pipe to radiator should be so run that they will be outside of the heating chamber and cold air supply. If the return main is dropped down within the cold air supply or near it, there is a possibility of it freezing. There is little to fear from frost with the indirect steam radiators placed in the manner described above, even though the cold air opening should be fully open and the steam in the boiler run down, as there is nothing to freeze beyond a small amount of vapor. It is seldom satisfactory to attempt to heat two rooms from one radiator. It is always better to have the radiator proportioned to the size of the room to be warmed and take from it one hot air pipe. The action is then positive, there being no possibility of one pipe drawing all the air and leaving the other pipe inactive, or with a possible down current in it to the radiator.

Steam heating is generally done on the gravity system where the plant is put in for heating purposes only. Where there is a boiler used for power purposes, steam may be taken from it and reduced down so that it can be used with perfect safety and with good results in the ordinary gravity system of piping by returning the condensed water to the boiler by means of a pump. In such cases it is usual to make arrangements to use the exhaust steam from the cylinder of the engine with the back pressure valve set so as to keep a small pressure in the steam mains.

In large buildings where it is possible to have the steam plant thoroughly designed and with a surplus boiler power, very satisfactory heating may be had with steam, but where the boiler is not of large size and has a small amount of heating surface, it is very difficult to maintain the heat at anything like an average temperature.

HOW TO ESTIMATE.*

By W. H. Hodson.

FOLLOWING is the remaining portion of the specification and bills of quantities accompanying the drawings of Public School on Gladstone Avenue, Toronto, published in the CANADIAN ARCHITECT AND BUILDER for February:

BLACKBOARDS.

Provide and fix ground work of blackboard on sliding door composed of six sheets of ¼ thick teather board 30 in. x 36 in. jointed and glued on to large door panel 36 in. x 15 ft. long, and left in readiness to receive composition paste to be put on by the School Board. (This leather board can be procured from the establishment of P. Jacobi, 5 Wellington St. east, city, at 15 cents per pound.) At the platform end of seven class rooms there will be slate blackboards 4 ft. high and 16 ft. long, composed of four slates ½ of an inch thick, jointed and packed and fitted to an even and true surface, and to be of Rockland slate of best quality, and to be approved by the architect and the inspector of city Public schools. These slates to be secured in position by wooden stop screws or with round head screws. Provide and fix moulded casing around all blackboards, both slate and plaster composition, in all class rooms, also ⅞ x 3 in. ground at back of slate board. The casing around blackboard to be 4 x 1¾ in., and to cope into side of architrave and to be moulded in same manner. For amount of composition blackboards see plasterer's specifications. The blackboards will extend along both sides and ends of each class room. The carpenter's tenders are to state the deduction of the slate if not required.

BRICKWORK.

All brick used in the works are to be of the best quality of Carlton brick, and (except otherwise specified) to be of a deep red color and to be hard and well burnt and free from lime and other defects. All outer walls and chimney stacks are to be faced up with "picked" hard and deep red colored "face brick." No soft brick will be allowed in the work, and are not to be brought upon the ground, but if any should be brought there, they are to be immediately removed. The mortar is to be composed of the best quality of coarse, clean sharp grit sand, and fresh burnt lime, in the proportion of 2½ of sand to one of lime, mixed with a proper quantity of clean water and thoroughly incorporated and tempered together. Build all brick walls as shown upon drawings and in accordance with the dimensions figured on plans and sections. The brickwork is to be laid up so as to gauge four courses to every 11½ in. in height, and to be carried up uniformly throughout the building. Every course of brick is to be laid in a full bed of mortar, and to be thoroughly flushed in with mortar at all cross and other joints. The walls are to be built in English bond for all partition walls, and for the inner portion of all external walls, but the outer face of all external walls is to be built "American" or "Stretcher" bond, the face brick being clipped to receive diagonal binders continuously on every 5th course. The walls and chimney stacks are to be carred up plumb, square and true, built to a line on both sides, particularly the face of all outer walls which are to be built fair and true, with each and every course laid with close and level joints. The inner face of outer walls are to be finished for plastering on; also both faces of all inner or partition walls in same manner. All the outer or foundation walls of basement are to be lined up with brickwork one-half brick or 4½ in. in thickness, tied into the stone work with a double heading course at the floor line, midway up, and at ceiling line of basement, and midway between these double heading courses to have a single heading course, making three double and two single heading courses for the whole height of basement storey. This brick lining will be composed of the best quality of picked hard grey brick, laid with level and fair close joints well bedded in mortar and the joints neatly struck with the trowel. The partition walls in basement, also the chimney breasts, are to be faced up "grey" brick, as above described, and pointed in the same manner, as there will be no plastering on basement walls. The bricklayer will provide for and execute all brickwork in connection with the Smead-Dowd heating and ventilating apparatus as indicated by the drawings and in accordance with the plans and specifications of such heating and ventilating apparatus hereto appended. The bricks used in connection with the above mentioned heating and ventilating apparatus are to be of the very best quality of picked hard and well shaped, red and grey brick in such proportion as may be required, to be built in a shapely and workmanlike manner, with close joints, neatly struck with the trowel. The walls for the air chambers and furnaces will be from 9 in. to 13½ in. in thickness, and extending from floor to ceiling, and all built square, true and plumb. Build the large ventilating and smoke stacks as shown per plans, elevation and sections, and in accordance with the dimensions figured on same. These stacks are to be built with picked hard brick, and the inside of same carefully and thoroughly parged with mortar, and so as to render the same even and smooth inside.

*This series of articles commenced in November, 1891.

The upper portion of these stacks is to be parged with Portland cement, say the upper 6 ft. of same, and all the sailing and hose courses, capping and belfry archway, &c., all to be laid in Portland cement, and all the joints and weatherings made and pointed in the most careful and thorough manner. Provide and build in sheet iron smoke pipe collars, four of them (14 in.) diameter in smoke flues in basement, wire rimmed on the outside and 9 in. deep and rim round same with ½ brick arch. Provide and build in a cast iron plate division between the smoke and ventilating flues in each stack as shown per drawings, extending from the basement floor level to top of stack above roof. These plates will be ⅜ in. to ¾ in. thick, 2 ft. 6 in. wide, and from 2 ft. to 2½ ft. in height, each made with a groove along the upper edge of each plate. Provide and build in cast iron soot doors and frames to same in bottom of each smoke flue, 14 in. square or larger, and provide and build manhole doorway in bottom of each ventilating flue, say 2 ft. 6 in. x 4 ft., arched over and provided with a fine tooled or rubbed stone head, 6 in. x 14 in. x 3 ft. 6 in. long. Provide and build an air duct under the basement floor in each closet room (two of them), having an area of 12 ft. each inside, and the length required as indicated on drawings. These ducts will be about 3 ft. in depth by 4 in. wide, built with picked hard brick and laid in Portland cement mortar; to have 9 in. wall at one side (the walls of building forming the other side) and to have a brick bottom laid on the flat and grouted with cement. Connect these ducts with the ventilating flue at the bottom of same with an opening 3 ft. x 4 ft., capped over with a tooled stone cap 12 in. x 14 in. x 5 ft. 6 in. in length. The foundation of the walls of building forming one side of these air ducts, and through which the same has to pass to reach the bottom of ventilating stack, are to have the extra depth required for that purpose, viz., 3 ft. Build all hot air flues leading from the basement up to the ground and first floors as indicated by the drawings; to be built in the most careful manner and thoroughly and smoothly parged inside with mortar. Build in all register frames and collars, &c., furnished by the contractors for heating apparatus and as indicated by the plans of heating. Provide and build in ½ in. round by 8 in. long, climbing irons in the brickwork of ventilating flues, every 6th course in height, alternately on each side of flue and placed about 9 in. from one end of same. Also provide and build manhole opening into each ventilating flue immediately above the attic joists, say 2 ft. 3 in. x 4 ft. high, with two rimmed arches over same on 2 x ½ x 4 ft. iron bar, and set frames to same pointed by carpenter. The rear basement wall will on any future extension of the building become an inside partition wall, and will therefore be built entirely of *brick* instead of stone, and will be of picked hard burnt brick carefully selected and the face bricks laid in Portland cement. This wall will be 18 in. in thickness, as figured on drawings. Build area walls of picked hard brick to rear entrance and rear basement entrance steps, as shown per drawings; also brick parapet walls at side of steps, and provide and build in ½ in. x 18 in. iron anchor bolts (27 of them) with ½ x 4 in. cross piece at bottom to secure coping to above walls. Provide and build parapet walls of brick to side of front entrance steps, as shown per drawings, and provide and build in ½ in. bolts (12 in number), 6 to each set of steps to anchor down the coping to same and as described for coping to rear steps. Build all belt, string and sailing courses, pilasters, &c., to outer walls, as shown per elevations; also all aprons to underside of window sills, the latter cut and rubbed to shape indicated and as per details to be furnished as required. Build water table plinth to base of brickwork, as shown per elevations, with the top course of moulded splayed brick with the top bed of same laid in Portland cement. Arches to window and door openings, also relieving arches in rear wall of building, to be 13½ in. and 9 in. in height respectively, as indicated by drawing; to be cut and guaged and with soffits rubbed and finished in best manner. Turn relieving arches two ½ brick rims in height to inside of all window and door openings to have a camber of not less than 6 in., formed on brick cores on top of straight lintels. Turn brick arches across the corridors on both stories as indicated by dotted lines on drawings, segmental in form and 13½ in. in height. The inside of front porches are to be faced up with picked, clean and even colored white brick laid stretcher bond in putty joints and lead jointed, and the inside arches showing in same porches to be finished in same manner; also that portion of outer main wall showing on the inside of porches. The outer face of all external walls (except the face of rear wall) will be dry tuck pointed in the very best manner, the joints being raked out full ½ in. deep as the work progresses, and when ready for the pointing to be stopped in with putty mortar specially prepared and colored a dark Indian red or other color to be selected and approved by the architect. The stopping for tuck pointing is to be colored with best "Venetian" red, and a sample piece of the work is to be done and approved by the architects before the regular work is begun. It is to be distinctly understood that a first class job in every respect is required, and that none other will be accepted by the architects. The face of rear wall is to be laid up with even colored brick with close and true joints and struck with the trowel in a neat and workmanlike manner. Beam filling is to be carried to top of joists and to roof boarding in all cases, and as to latter to be pointed with mortar so as to render the same air tight. Carefully and thoroughly flush into all window and door frames as the brickwork progresses, and carefully preserve the staying of all frames. Build in all bond strips, joists, plates, lintels, wood blocks, &c., required by carpenter, and build chases for water and waste pipes required by plumber. Provide and lay the basement floors throughout with concrete and Portland cement, and as follows, viz.: First clean off the earth floors removing all wood cuttings and other rubbish, and carefully level the ground, grading the same towards the weeping drains; then provide and lay over the whole surface of floors a bed of fine broken brick and coarse gravel well mixed together, to a depth of at least four inches, all well rammed down; then over this lay a bed of fine gravel (screened) one inch in thickness mixed with Portland cement in the proportion of one of cement to three of gravel, and over this float on a coat of Portland cement one inch in thickness mixed with clean sharp sand, in the proportion of one to two. The top coat of cement is to be floated to sand and trowelled down to a smooth and level surface throughout, and to be protected until thoroughly set. The cement floor in each room is to be graded to the centre and provided with a 6 in. cast iron grating connected with the drains underneath to carry off water when the floors are washed. All the above concrete and cement floors are to be executed with the very best of Portland cement and other materials, and in the most workmanlike and thorough manner. The contractor or contractors are to provide good and sufficient scaffolding, to be approved by the architects, and be left up for the other trades. He or they will conform to the requirements and provisions of the building by-laws of the city. The chimney stacks are to be tuck pointed as described for walls, in the most careful manner, and the stone base and cap set and pointed in Portland cement. As soon as the tuck pointing is done, or sooner if required by the architect, the contractor will remove all bricklayers' surplus materials, and all rubbish and plant from the premises, and will clean up the lot and such portions of the street fronts used by him, and will also clean out the basement and other flats of the building, removing from same all bricklayers' rubbish, surplus materials and plant, &c. The whole of the bricklayers' work is to be executed in the most thorough and workmanlike manner and complete in every respect, the contractor furnishing all necessary and proper materials, scaffolding, tools and labour, and executing all the works called for by the plans and specifications, comprehending what might reasonably be implied though not particularly mentioned in the specifications or shown on the drawings.

CUT STONEWORK.

Provide and set all cut stonework required throughout the building complete in all respects, and as follows, viz.: All window sills to be of Credit Valley brown stone, 6 in. x 10 in., fine tooled and weathered on top and throated under, but to be rock face on the face and to project 2 in. from face of brickwork. All windows above the basement and all entrance doors to have 6 in. x 12 in. stone heads of Credit Valley brown stone, fine tooled on the soffit or under side, and to be back checked and picked to a face on the back side to fit to frames and lintels, but to be left rock faced on the front. The two basement rear entrance doors to have 12 in. x 6 in. tooled or rubbed Berea heads. The chimney and ventilating stacks will have 6 in. thick base and cap stone, as shown per elevations and sections; to be fine tooled and weathered on the top side and throated under. Cut left rock face on the edges. These cap and bases will be formed in the number of stones each as shown per details, to be cramped and leaded together and the joints set and pointed with Portland cement. The base stone will form the floor of belfry between the two vent stacks, and will have a 2 to 3 in. hole drilled through same and a piece of 2 in., 8 lb. lead pipe inserted in same and neatly dressed down and flanged to the stonework, and to pass down about three or four feet below for bell rope to pass through. Provide and set two Berea stone corbels 14 in. x 24 in. x 12 in. to carry the point of main rafters at side of ventilating stacks; to be tooled work. Provide and set fine tooled Berea stone sills to basement entrance doors, 6 in. x 4 ft. 6 in. x 18 in. The sills to rear windows are to be of fine tooled Berea, weathered and throated. Provide and fix inscription stone to front of building 21 in. x 6 in. and 14 ft. 9 in. in length, with the inscription "City Public School" cut in same in letters 9 in. high, inch wide and ½ in. deep, and capitals 14 in. high, 1¼ in. wide and inch deep. This stone will be of Credit Valley brown stone, rock faced on the margin and fine tooled in the centre to receive the lettering. Provide and fix cap stones of rubbed Berea stone 3 in. thick, to cover the top of hot air flue projections on the two rear corners of building. There will be four of these stones, two of them 14 in. x 36 in. and two of them 14 in. x 48 in., to be weathered on top.

GALVANIZED IRONWORK.

Provide best quality of "Iron" brand or Gospel Oak No. 26 B.W.G. galvanized iron, and form and execute and complete in the most substantial and workmanlike manner all the galvanized ironwork hereinafter described. The deck roof to be covered with galvanized iron formed in long sheets with joints made on 2 in. rolls with caps to same nailed and soldered, and with false or expansion rolls between same. Cross joints to be lock jointed and soldered in best manner. Turn the iron down 4 in. over slate and form moulding at junction of deck and slate roof as per marginal section, all well stayed, nailed and soldered, and with spring or wind seam along the slate apron. Line all vallies with galvanized iron, 20 in. in width, and under same lay one ply of tarred felt 30 in. wide properly nailed down. Lay apron of galvanized iron to all eaves 10 in. wide, turned up under slating and nailed to roof boarding and dressed down into eave troughs. Eave troughs throughout to be oval and fillet shaped, with back to same 4 in. above level of trough, all well secured to facia of cornice with long spikes through galvanized iron trales. Eave troughs to be well soldered at all cross joints. Down pipes to be Douglas Bros. patent octagon shaped, secured with patent hold fast spikes to brick walls, and to be carried down 2 ft. below grade of ground and hanged and cemented into drain pipes. There will be six stacks of 5 in. octagon down pipes as above described, and two small stacks of same from the front porch roof; also four stacks of 4 in. round down pipe from play-shed roofs, the latter to have shoes to same to waste onto the planking. The main roof gutters to be 6 in. moulded, the porch 5 in. do. and the sheds 5 in., all complete. Provide and fix 10 in. wide cloak flashings to all roofs abutting against brickwork; also continual aprons where required around the base of the ventilating stacks and belfry, the iron to be tucked one inch into joints of brickwork and wedged with iron wedges, and cemented with Portland cement, and dressed down and fitted neat and close to brickwork, and where practicable to be stepped with the brick courses. Provide and fix galvanized iron cresting (moulded) to belfry ridge in accordance with details, and flash same to brickwork also moulded eave moulding to same as per drawings. All the galvanized ironwork is to be executed as expeditiously as the progress of the building will admit of, and in the most substantial and workmanlike manner, complete in all respects. Provide and cover the man-hole opening in deck roof both sides and top; sides 12 in. high and top about 3 ft. square with galvanized iron, all fitted and finished in best manner.

SLATING.

Provide and slate the roof (excepting those of the play sheds) with the best description of Canadian slate from the Melbourne Quarries. Slates to be 10 in. x 20 in., laid on single ply of tarred felt with double lap leaving 10 in. to the weather. Each slate to be nailed with two galvanized iron nails, and to be laid with double row at eaves. Trim the slate to a line on both sides of all vallies, and cut and lay all hips with cut close chamfer and point same with slate colored plastic cement. Provide and lay 10 in. wide step flashings of galvanized iron to all slating abutting against brickwork, and in most careful manner. Carefully lay and close nail the tarred felting so as to cover the roof boarding at all points, and lay double straddle thickness of felting over all hips, vallies and ridges. Execute all other work necessary to render the slating complete in every respect. Examine the slating on the completion of the work of all other trades, and make good any broken or displaced slate, and clean out and remove all broken slate and cuttings of same from eave troughs and down pipes and vallies. Remove all surplus slate and cuttings, &c., from the premises on completion of the slating. The belfry roof is to be laid with round tailed red tiles laid in cement and all well cemented at joints and against brickwork.

PLUMBING WORK.

Provide and lay in from street main, clear of frost and with stop and waste cock boxed in and packed, &c., ¾ in. 6-lb. lead water service to basement of building, with *separate* ⅝ in. 10 lb. branch service from same to the drinking stands in basement, lunch rooms and to ground and first floor corridors, and in all cases to be carried on neat dressed and moulded boards fastened to wall and ceilings, and where required to be cased in the woodwork provided by carpenter. The service pipes must be arranged so that the same can be emptied with proper stop and waste cocks. Provide and fix in each lunch room or basement one of Mott's patterns of cast iron enamelled drinking stands, No. 93 pattern, page 42 of Mott's catalogue, 1881 edition. Also provide and fit up in the recess next to ventilating stacks on ground and first floor corridors, Mott's pattern of cast iron sectional urinals (8 ft. long each) to be used as drinking stands, to be supported on proper dressed boards secured to wainscoting; see Mott's catalogue No. 257-8 pattern, page 127, edition of 1881; these drinking stands to have ⅝ best pattern self-acting spring cocks, nickel plated, two to each stand in basement and six to each stand on ground and first floors, (16 in all). Each stand to have 1½ in. 6 lb. lead waste and trap and screw

to same complete, and connected to drain under basement floor. The above described plumbing work to be of the most substantial character and finished in best manner, and to include sixteen heavy metal drinking cups with strong chain attachments to the drinking stands complete.

PLASTERING WORK.

Provide and render the inside of all outer walls before the same are lathed (basement walls excepted) with one good heavy coat of brown hair mortar. Provide and lay in "pugging" between ground floor and first floor joists for *deafening*, to be composed of coarse mortar and spread in with a mould and so as to be two inches thick in the centre and three inches at the sides, as shown per marginal section. Provide and lath all outer walls (basement walls excepted) and all ceilings and soffits of stairs with best quality of sawn pine lath 1 in. wide for ceilings and 1½ wide for walls, to be laid on with at least 5-16 of an inch keep joint and breaking joints every sixth lath; lath to be well seasoned and free from sap and other defects. Render, float and set, in best "*three coat*" work, *all* walls and ceilings and soffit of stairs throughout the building (basement excepted), and finish the same in best "hard white finish," all thoroughly trowelled. The basement ceiling throughout is to be plastered in two good coats of plaster, floated and set in hard sand finish, all well trowelled. The mortar for plastering is to be composed of the best quality of lime and clean sharp sand, mixed with an ample quantity of long animal hair, all thoroughly incorporated together. The hard white finish or putty coat is to consist of best plaster of Paris, with a sufficient quantity of *washed white* sand mixed with same. The lathing on outer walls will not be carried below the top of wainscotting, but the plasterer will float on a second coat of brown mortar over the face of the first rough coat, and will carefully point and flush in around frame and all points where necessary. All the foregoing described plastering is to be of the very best and most substantial description and quality, and complete in every respect. The plasterer will provide for and remove all plaster droppings and other plasterers' rubbish and thoroughly clean out the building on completion of the plastering work, doing each room and corridor as the same are completed.

COMPOSITION BLACKBOARDS.

All the class rooms, eight of them, will have the best description and quality of composition blackboards, made under the directions and supervision of the Inspector of Public Schools of the city of Toronto. These composition blackboards will extend around the four walls of each class room, excepting 15 ft. in length of the platform end of each class room, which will be composed of slate. The width or height of the composition blackboards will be 3 ft. 6 in., excepting the 10 ft. in length at the platform end of each class room, which will be 4 ft. in height. The slate blackboards will be provided and set up by the carpenter, but the plasterer will float the walls at back of same and will finish the composition boards up to and fair and true with the face of the slate. The sum of $150 of the contract amount for plastering will be retained by the School Board until the composition blackboards have been properly tested and approved by the Inspector of Public Schools of the city of Toronto, upon whose certificate of the efficiency of the blackboards the above mentioned sum of $150 will be paid to the contractor.

PAINTING AND GLAZING.

All dressed woodwork is to be well primed, stopped with oil putty and knotted with best spirit knotting preparatory to the regular painting. For particulars of woodwork examine the drawings and read carpenter and joiners specification. All frames and other finished woodwork is to be primed as soon as prepared by the carpenter. All sash are to be primed and glazed as soon as fitted by the carpenter, and carefully stored away until ready for hanging. All dressed woodwork inside and outside of building, including all the woodwork of stairs and entrance steps, also all the woodwork of the privy closets and conveniences in basement, is to be painted in the very best manner and style with the best brand of white lead and linseed oil paint colored to choice tints, to be approved by the architects, and as follows, viz.: The woodwork both inside and outside of building (excepting the inside of the basement) is to have (3) three good coats of paint in addition to the priming coat. The woodwork in basement will be painted (2) two good coats of paint in addition to the priming. All galvanized ironwork, including all gutters, down pipes, hips and vallies, and the deck of roof, is to be painted three good coats of paint, including the *priming* coat, which is to be of red lead. The woodwork of play sheds, viz., the cornice posts and braces to same, also the siding and batten to same, is to be painted two good coats of paint in addition to the priming coat, which is to be the same as described for the school building. The fence along the street frontage of school lot, 200 ft. in length and 4 ft. in height, will consist of open picket fence with gates to same and large corner posts, all dressed stuff. This fence will be primed and painted in (3) three good coats of paint, counting the priming as one coat, and as described for the building. The division fence dividing the play yards will be of dressed stuff, close board, 7 ft. high. This fence will be primed and painted same as described for the picket fence. The two front entrance doors to have four coats of paint and well rubbed down with pumice stone, and finished smooth and clean. Paint the mouldings around the blackboards extending along both sides and two ends of each class room same as described for other woodwork. The entrance door sills, and the treads of entrance steps and of stairs will be of oak, and the floors to ground and first floor stories will be of hardwood. These door sills, treads of steps and stairs, and the hardwood floors to the eight class rooms, and the two main corridors and entrance porches, will be twice coated with linseed oil laid on hot, say at a temperature of at least 130 degrees Fahrenheit, and thoroughly well rubbed in with woolen cloths until the same is hard and dry. The stair rails will be well rubbed down and coated with oil as above described, but with three coats of oil. Paint all exposed plumbing pipes and ironwork. Paint the brickwork at back of two false windows two good coats of paint as shall be directed. Provide for and give the walls of basement throughout, including the brickwork of the heating and ventilating apparatus, but excepting the inside of two coat rooms, two good heavy coats of fresh white lime whitewash. The painter will clean off all glass and woodwork, &c., which may have become spotted or stained, &c., during the operation of painting or white-washing.

GLASS AND GLAZING.

The glass used throughout the building is to be of the very best description and quality of *selected* 16 oz. Diamond Star brand of glass, all well cut in, puttied and back puttied, and finished in very best manner complete. The transom lights over all class room doors, and the glass to glass partitions across the upper corridor, also glass in basement entrance doors and to basement borrowed lights, will be glazed as above described. The sash are to be glazed as soon as hitted, and left to harden until ready for hanging. The whole of the painting and glazing is to be executed with the very best of materials and in the most thorough and workmanlike manner, and to the entire satisfaction of the architects in charge of the works. The tenders for painting and glazing of the school building, sheds and fencing are to provide for and include all the painting and glazing as specified, allowing for the work already executed, providing, however, for making good any defects in same so that the whole work shall be a good and workmanlike job and complete in all respects.

BILL OF QUANTITIES.

CARPENTER AND JOINER WORK.

	$	c.
39857 ft. of pine timber (board measure) in joists, rafters, plates, lintels, etc., and labor in same, as specified		
91 squares (100 ft.) of ⅞ in. G & T flooring, 3 in. wide, of white maple, complete		
4¼ squares of ⅞ in. G & T flooring, of maple, 6 in. x 2 in. beams (these beams are laid on cement floor) to privy closets, complete		
67½ squares of 1⅛ in. G & T roof boarding, 6 in. wide to main belfry, front and rear porches, etc., complete		
91 squares of ⅞ in. rough flooring, 10 in. wide		
7 squares of ⅞ in. maple raised teacher's platform, on 6 in. x 2 in. bearers, complete		
91 squares of 2 in. x 3 in. and 2 in. x 2 in. strapping, basement and ground ceilings, complete		
76¼ squares of 2 in. x 2½ in. strapping, ground and first floor walls, complete		
4 squares of sheeding at basement entrance and upper steps, roof complete		
275 running ft. of cornice to main roof, complete		
58 running ft. of moulding to gablets of main roof, complete		
308 running ft. of chained joists, 14 in. x 2 in., 1½ in. packing pieces spiked together, and 1 in. iron straining rod, 6 in. x 8 in. x ½ in. end plates, nuts and washers, ¾ in. iron bolts, 72 in number, complete		
1300 running ft. of ⅞ in. G & T narrow wainscotting mould cap and plinth, 3 ft. 6 in. in height, complete		
424 running ft. of ridge rolls and tilting pieces to valleys and eaves, complete		
70 running ft. of 1¼ in. iron gas piping, for hand-rail to main stairs, includes bracket and socket flanges to newel, complete		
20 running ft. of pine linth, 14 in. x 10 in., dressed, trussed on top and with inch iron rods, nuts, washers, etc., complete		
27 1⅜ in. stair steps, oak tread and 1 rest landing, strings, balustrading, V jointed wainscotting, capping, oak hand-rail, includes the balustrating of well, etc., chamfered posts 6 in. x 6 in., spandrail, 8 in. x 8 in. turned oak newel, etc., complete		
15 basement stair steps, oak tread, strings, balustrading, V jointed wainscotting, capping, hand-rail, includes the balustrading of well, etc., chamfered posts, 6 in. x 6 in., spandrail, 8 in. x 8 in. turned oak newels, etc., complete		
17 rear basement steps, 2 x 2 oak plank platform and supports, top, uprights, and diagonal rails, ¾ in. bolts to coping, strings, etc., complete as above		
18 rear entrance steps descending to basement, narrower, 14 in. x 3 in. pine chamfered coping bolted to wall and round oak roll planted on top, complete		
18 front porch entrance steps, 2 in. x 2 in. slatted treads, 1½ in. oak risers, strings, 2 platforms, oak parapets, and moulded coping, etc., complete		
2 2⅜ in. front entrance doors, 12 in. x 3 in. frames, lock and other hardware, etc., complete		
2 2¼ inside porch doors, frames, locks and other hardware, etc., complete		
1 2⅜ in. rear entrance door, frame, lock and other hardware, etc., complete		
2 2½ in. basement entrance sash doors, frames, locks and other hardware, etc., complete		
8 1¾ in. class room doors, frames and fanlight, steel spring latches and other hardware, etc., complete		
1 2⅜ in. sliding door, jambs, boxing, hardwood stop, ¾ in. half round sliding rail, wheels, etc., complete		
6 1¼ in. basement doors, frames, locks and other hardware, etc., complete		
4 1⅛ in. foul air chamber and vent shaft doors, frames, hinges and bolts, etc., complete		
17 1¼ in. basement windows, frames, hinges, pulleys, cords, plumb bob balance, bolts, etc., complete		
4 borrowed lights, frames, and with vertical iron bars to corridors in basement, etc., complete		
1 1¼ in. large half circle window, frame, mullion bars, etc., complete		
3 small circular sashes to porch and rear gable, etc., complete		
42 1¼ in. English sashes, ground and first floor, boxed frames, double hung, sash lines, weights, lifts, sash fasteners, etc., complete		
8 brass pull down hooks and poles, etc., complete		
2 rear porches to basement entrance steps, includes 6 x 6 in. dressed and chamfered posts, plates, and cross bearers, double sheeting, dressed rafters, facia and crown moulding, etc., complete		
48 wrought iron anchors, 36 in. x 2 in. x ½ in., one end turned up 6 in., two ⅞ in. bolts other end, etc., complete		
50 ¾ in. iron bolts, nuts, etc., to bent plates, etc., complete		
48 ventilating openings in base of wainscotting, wood frames and wire cloth screens complete		
29 privy closets—fit up with risers, seats, hinged covers, 1¼ G & T divisions and screens 36 ft. long, 6 ft. 6 in. high capped 3 in. x 3 in. chamfered posts from floor to ceiling, etc., complete		
42 small cupboards in class rooms, flock panel doors in two boxes, locks, fasteners, etc., shelving, mould cornice, etc., complete		
500 clothes hooks, and screws, etc, complete		
1 back board, dressed, to urinal, 6 ft. 3 ins. x 15 in. x 1¼ in., etc., complete		
Trimmings to stairs, ventilating stacks, fines, etc., double tusk frames, joists spiked together, 2 in. x ½ in. stirrup pins to stair well, etc., complete		
Trimming for man-hole, framed door, hinged on top, fasteners and hooks, includes step ladder to same, etc., complete		
Bracketting for galvanized iron cornice at belfry, etc., complete		
Provide and set all centres for brickbayers, stay frames, ease cut stone work as directed, etc., complete		
Carpenter to box in plumber's piping, do all cutting, etc., as required, and attend on other trades, etc., complete		
Temporary doors and fasteners and general care of building night and Sundays		
Dressing basement window lintels 2 faces and basement door 3 faces, complete		
Dressing wall face of bond timbers in basement		
1 blackboard on sliding door panel, 6 sheets of 1/4th in. thick leather 30 in. x 16 in., jointed and glued ready to receive composition		
7 blackboards of slate, 16 ft. x 4 ft., jointed, packed and fit to even surface, including mould casing, stops, round headed screws, separate price if used		
Mould casing to 560 ft. of composition blackboard		
State deduction for slate if not required in blackboards		

NOTE.—Beginning with bearing timbers, (undressed) the measure thus: joist 30 ft. x 10 in. x 3 = equal to 6 ft. 3 in. cube—to bring into board measure; multiply by 12 (for a 1 foot square) gives the board measure 75 feet. Flooring, roof boarding, studding, furring, etc., measured length and breadth, thus: 25 ft. x 16 ft. gives = 400 ft. equal to 4 squares of 10 ft. x 10 ft. Lineal measure or running feet applies to cornices and dressed work generally, the sizes stated either in quantities or specification. Items in numbers, such as doors, windows, &c., as above.

BRICKWORK.

	$	c.
43,000 hard Carlton face brick, picked, for 3 faces, pointed, red putty mortar, including chimney stacks		
326,500 red and grey hard brick, picked, wall lining, etc., etc., trowel pointed, etc.		
2,900 clean, even colored white brick, to front porches, lead jointed		
2,200 hard brick to foul air duct, in cement		
30 supl. yds. of brick on flat, grouted in cement		
483 supl. yds. of 4 in. concrete and 1 in. Portland cement floor		
223 running ft. of water table, top course mould brick in cement		
4 14 in. x 9 in. smoke pipe collars of sheet iron to flues, with wire rims, etc.		
2 cast iron plate divisions to smoke and ventilating flues, ⅜ in. to ¼ in. x 2 ft. 6 in. x 2 ft. to 2 ft. 6 in., upper edge grooved, total height 80 ft. 9 in.		
2 cast iron soot doors and frames, 14 in. square		
2 man-hole doorways, stone head 3 ft. 6 in. x 14 in. x 6 in.		
1 tooled cap stone, 5 ft. 6 in. x 14 in. x 12 in., at flue connections		
2 4 ft. x 2 in. x ½ in. iron bars to arches at man-hole openings		
27 ¼ in. x 18 in. iron anchor bolts, with ½ in. x 4 in. cross pieces		
12 ¾ in. iron bolts to anchor down coping of rear steps		
63 arches to window and door openings		
2 large arches across corridors		
61 relieving arches to window and door openings		
2 large relieving arches in rear wall		
1 6 in. cast iron grating to drain		
Building in registers, frames, collars, etc., furnished by the contractor for heating		
Provide and build in 8 in. x ¾ in. climbing irons, about 60 in number, to stack		
Bedding to window and door frames throughout, bond strips, plates, lintels, wood, bricks, etc., etc.		
Provide and construct scaffolding as required and to be left up for other trades		
Setting (only) stone bases and caps to chimney stack in Portland cement		
Removal surplus materials, rubbish plant, etc., clean out basement, etc., etc.		
1 semi-circular double arch to upper front window		
2 smaller circular arches to porch		
2 semi-circular arches at belfry		
8 small circular, to stacks		

NOTE.—Brickwork is measured cube and in Montreal the number of bricks given in estimating, is 20 bricks to the cube foot, and is ascertained thus:

6 bricks long say 4' 0"
9 " high " 2' 0"

54
3 brick thick

8' 0" as divisor.

$$8\left[\frac{162}{16}\right]$$ to the foot.

The openings are measured and deducted from the solid work. Concrete when not deep is measured by the superficial yard, thus, 3 ft. by 3 ft. gives one yard. Concrete in heavy work is measured cube, 3 ft. x 3 ft. x 3 ft., or 27 feet to the cubic yard. Arches, etc., are given in numbers and other items noted as above.

CUT STONEWORK.

	$	c.
37 Credit Valley brown cut stone sills, 5 ft. 3 in. x 10 in. x 6 in., weathered and throated, rock faced		
4 Credit Valley brown cut stone sills, 7 ft. x 10 in. x 6 in., weathered, throated and rock face		
16 Credit Valley brown cut stone sills, 4 ft. 6 in. x 10 in. x 6 in., weathered, throated and rock face, to basement		
37 Credit Valley brown cut stone heads, 5 ft. 6 in. x 12 in. x 6 in., soffit tooled		
4 Credit Valley brown cut stone heads, 7 ft. 3 in. x 12 in. x 6 in., soffit tooled		
2 Credit Valley brown cut stone sills, 4 ft. 9 in. x 10 in. x 6 in., weathered and throated, rock faced		
2 Credit Valley brown cut stone heads, 4 ft. 9 in. x 12 in. x 6 in., soffit tooled		
2 Berea stone door heads, 5 ft. 0 in. x 16 in. x 12 in., to basement		
2 Berea stone corbels, 24 in. x 14 in. x 12 in., to rafters		
2 cap stones to air-flues, 3 ft. x 1 ft. 2 in. x 3 in., weathered		
2 cap stones to air flues, 4 ft. x 1 ft. 2 in. x 3 in., weathered		
2 tooled Berea stone door sills, 4 ft. 6 in. x 18 in. x 6 in.		
1 Credit Valley brown inscription stone (City Public School), 14 ft. 9 in. x 21 in. x 6 in., fine tooled for lettering, rock face, margin, lettering, etc., complete		
19 running ft. of sill and belt course to front window		
1 base stone at belfry floor (17 ft. x 11 ft.) in different size stones, tooled, weathered and throated, including 1-3 in. bulk and 5 ft. of 8 lbs. lead pipe inserted, dressed down to stone		
2 cap stones to stacks (10 ft. 3 in. x 4 ft. 6 in.) in different size stones, weathered and throated, crumped, leaded and pointed in Portland cement		

NOTE.—Cut stone is measured superficial, that is, square, thus: 20 ft. x 20 ft. gives 400 superficial feet. Sills, heads, steps, etc., are counted and the number given according to sizes and quality of work, as shown in above items of quantities.

SLATING AND GALVANIZED IRONWORK.

	$	c.
65½ squares of Melbourne slating on 1 ply tarred felt		
5 squares of 26 oz. galvanized iron, deck roof includes 2 in. rolls, solder, etc.		
1 square of red tiling (belfry roof) in cement		
78 lineal ft. of galvanized iron mould nosing, seamed and soldered		
132 lineal ft. of galvanized iron valley lining, 20 in. on tarred felt 30 in. wide		
275 lineal ft. of galvanized iron eaves, apron 10 in. dressed down		
292 lineal ft. of galvanized iron 6 in. mould gutter, soldered and spiked		
37 lineal ft. of galvanized iron 5 in. mould gutter to porch		
280 lineal ft. of galvanized iron 5 in. Douglas down pipes (octagon) cemented to drain		
133 lineal ft. of galvanized iron cloak flashings and aprons, cemented and dressed down		
36 lineal ft. of cresting and eave mould (belfry ridge), galvanized iron		
1 man-hole lift, 3 ft. x 3 ft., covered with galvanized iron top and sides		

NOTE.—Measured, and contents given in squares, before mentioned, lineal measure, also, and the sizes as above.

PLUMBING.

	$	c.
200 lineal ft. ⅝ in. lead service pipe, 6 lbs. to the yard		
90 lineal ft. 1⅓ in. lead waste pipe, 6 lbs. to the yard		
2 Motts enamelled drinking stands, No. 93, basement, complete		
2 Motts urinals (used as drinking stands), No. 257-8 ground and first storey		
2 stop and waste cocks to pipes, etc., complete		
1 urinal in basement, complete		
16 ⅝ nickle self-acting cocks, complete		
6 traps and screws to waste pipes, complete		
1 stop and waste cock to main, boxed in, complete		
16 heavy metal drinking cups and chains, complete		
¾ in. lead main pipe, 6 lbs. to the yard, at per lineal foot, complete		

NOTE.—In these works there are many and various items, as will be noted in the above, comprising lineal measure and numbers.

PLASTERING.

	$	c.
740 supl. yds. of 1 coat (heavy) on walls, flush into frames, etc., before lathing		
900 supl. yds. of pugging, 2 to 3 in.		
2970 supl. yds. of 3 coat work, (white finish)		
480 supl. yds. of 2 coat work, basement ceilings		
560 lineal ft. of composition blackboard, 3 ft. x 6 in. high		
112 lineal ft. of composition blackboard, 4 ft. high, separate price in lieu of slate		
Removing and cleaning throughout at finish of plaster work, complete		

NOTE.—Superficial measure is given, that is, the walls and ceilings are measured through, openings are measured and deducted from same, showing the net number of superficial yards done. Cornices and other moulds in plaster are lineal measure, the girths of same added for mitreing internal and external angles. Centres are numbered, giving diameters.

PAINTING AND GLAZING.

	$	c.
1300 supl. yds. of priming and 3 coats painting		
265 supl. yds. of priming and 2 coats painting		
236 supl. yds. of priming and 3 coats painting, on galvanized iron work		
20 supl. yds. of priming and 4 coats, rubbed down with pumice stone.		
718 supl. yds. of 2 coats oiling, floors, steps, sills, etc.		
32 " of 3 " stair rails		
906 " of 2 coats lime washing, basement walls		
Cleaning off generally glass and woodwork, etc., at completion of work		
1356 supl. ft. of 16 oz. Diamond Star brand glass		

NOTE.—Painting measured and given, superficial yards in quantities as shown. Glazing, measure superficial feet, and in plate glass at per pane, with size stated.

CONCRETE BUILDING.

THE members of the Technical Society of the Pacific Coast lately went to Palo Alto on the invitation of E. L. Ransome, who has nearly completed two large concrete buildings for the Leland Sanford, Jr., University. One of these is the girls' dormority. The larger one is the museum building, and is the finest piece of building concrete work yet done in this vicinity. The structure is absolutely fireproof, and intended also to be earthquake-proof. It is built on the system patented by Mr. Ransome, so as to be a homogeneous structure as to walls and partitions, there being no joints. Twisted iron rods are used for additional strength where necessary. The cement is mixed in the Ransome patent mixer and elevated to points where used. A large force of men has been at work on this building for sometime and it is now almost complete. Even the interior arches and ceilings are of concrete. The stairways are made of concrete, and these will be covered with marble steps. The hallways will be finished in marble over the concrete. There is no wood anywhere in the building, the window frames, etc., being of metal. The exterior is furnished with a smooth coat of cement to resemble brownstone. The heavy columns of the entrances are, like the main structure, of concrete, and the statuary to surmount the building is moulded of the same material.

There are two concrete buildings now and others are to follow. They were built by contract by Messrs. Ransome & Cushing in an exceedingly short space of time. Stone buildings of equal dimensions would have taken three or four times longer to construct.—*Scientific American.*

To make a red wash for brick on a cheap job, says V.B.G. in *Exchange:* Take 4 ozs. of brown glue (none but the best should be used), melt in the usual way and dilute with water to 4 gals. While the glue water is hot dissolve it in 1 lb. of alum. Then stir in the Venetian red, yellow ochre or Spanish brown in proportions to get the color you desire, and the proper consistency to spread well. This wash should go on in thin coats. I have known instances where this wash seemed to wear like paint. I prefer a mixture of Venetian and ochre for colors.

The Toronto Art Students' League has elected the following officers for the ensuing year, R. H. Holmes, president; Mr. W. D. Blatchley, vice-president; C. W. Jeffries, treasurer; W. W. Alexander, corresponding secretary; D. F. Thomson, recording secretary. We are pleased to hear that the Society is making satisfactory progress.

Kiln-baked bricks occur in the ruins of ancient Babylon, and were pressed out of a wooden mould. Some have been found bearing the name and title of Nebuchadnezzar. In the ruins of Babylon it is claimed that original Chaldaic accounts of the genesis and of the deluge have been discovered stamped in cuneiform characters on clay tablets.

CANADIAN ARCHITECT AND BUILDER.

VOL. V.—No. IV. TORONTO AND MONTREAL, CANADA, APRIL, 1892. PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),

PUBLISHED ON THE THIRD SATURDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher.

14 King Street West, - TORONTO, CANADA.

64 TEMPLE BUILDING, MONTREAL.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

THE journeymen painters and decorators of Winnipeg are at present on strike owing to the refusal of the employers to grant an increase of wages amounting to 2½ cents per hour all round. The scale heretofore in force has been 22½, 25, 27½ and 30 cents per hour.

THE *Australasian Builder* suggests that New South Wales copy the example of British Columbia by sending to the World's Fair specimens of its native timbers. Our Pacific province will build a structure which will contain all the varieties of native woods. It will be built in sections of contrasting woods, neatly mortised together; the roof will consist of native slate and a variety of cedar shingles. The building will be shipped to Chicago in sections, and will be put together on the fair grounds.

ADDITIONAL interest would be given to the annual meetings of the O. A. A. if to the usual exhibition of drawings there was added an exhibit of building materials and appliances. We understand that an upper flat in the School of Science might be utilized for this purpose. Such an exhibit would be especially interesting to members of the Association practising in the towns and smaller cities of the Province, who are without the opportunities open to architects in large cities of becoming familiar with the latest improvements in materials. An exhibit of this character might assist in bringing to the annual meetings a larger number of the members resident outside of Toronto. There is little reason to doubt that manufacturers and dealers would be pleased to exhibit if the necessary accommodation for the purpose was provided.

IT was announced early this month by Sir John Thomson that the Dominion Government intends to erect a statue to Sir John Macdonald on Parliament Square, Ottawa, and the announcement was received by all members of the House with great satisfaction. What the intention of the Government may be as to the employment of an artist for this work we have not heard; the money has yet to be voted for the purpose, and until that is done no decision will be made. It is, however, earnestly to be hoped that the best talent in the Dominion may be secured for the work—and that there is talent capable of executing the work to be found within our boundries there can be no reason to doubt. No one but a Canadian should have the commission for such a thoroughly national monument, and every facility should be given to Canadian artists to enable them by competition or otherwise to show that they possess the necessary talent.

THE appointment of Prof. Saunders as Canadian Commissioner to the Columbian Exposition or "World's Fair" will be a satisfaction to every one interested. Prof. Saunders has had great experience in these matters, having acted as our Commissioner in nearly all the exhibitions Canada has taken part in, and we feel sure that so far as the Commissioner is concerned, the exhibition of Canadian products and manufactures will be a success. As to exactly what the arrangements are for our exhibits, we have not yet been able to find out; very little seems to have been done as yet. The Montreal Board of Trade are taking the matter up on behalf of or in the interests of the city, and it is to be hoped that other cities will now begin to interest themselves in the matter. All loyal Canadians should do their best to make this exhibition a success, sinking petty jealousies with regard to our neighbor and remembering only the great interests of Canada.

SOME extracts from an address on "Native versus Natural Cements," are printed in this issue. The statements and deductions contained therein must prove of interest to many of our readers. Our attention has lately been called to the results of tests of Canadian cements and artificial cements under the direction of the Dominion Government engineers. These tests show that the native cement rapidly improves in quality with age. For example, while in a seven days test the tensile strength of native cement is shown to have been less than one-third that of English artificial cement, at the end of twelve months the strength of the two cements was about equal, showing that age improves to a wonderful degree the quality of the native article, which also has the advantage in point of cheapness. We would be pleased to know how far Canadian engineers and architects have gone in the direction of proving for themselves the merits of the two varieties.

THE opinion seems to be very general that work in the building trade will be quiet this year. "Things are awfully quiet" we hear remarked half a dozen times every day, with reference to all lines of business. The record of building permits taken out at the City Hall is very incomprehensible. It is stated that permits have been taken out for so many thousand dollars worth of work making a considerable increase over the amount shown by the permits issued for the same period last year. But where is the work? As it is well known there is a great deal of irregularity in the matter of taking out permits. Many people do not take any out at all until the building has been completed, and then again, many works for which permits are granted are not carried out, so that as an opportunity of comparison, the permit book is not of much value. There are several large buildings drawing near completion, but we hear of few if any as likely to be begun this year. However the season is young as yet, and we hope matters may improve as it gets older.

IN view of the penalties to which they were liable to become subject under the Employers' Liability Act, the master builders of Melbourne, Australia, arrived at an understanding with their workmen by which an insurance of £50 against accident of whatever kind was to be carried by each workman. Towards the cost of this insurance both employer and employee were asked to contribute, the latter in the proportion of sixpence per week. This arrangement, while seemingly advantageous to both parties, did not long satisfy the workmen, who began to grumble about the weekly payment of sixpence. The employers opened negotiations with the insurance company for the cancellation of the policies. Despite the willingness they thus manifested to terminate the arrangement as soon as possible, the stone masons went out on strike because it was not ended immediately. Exhibitions of unreasonableness have not been wanting on the part of employees in the building trades, but this certainly deserves to be classed as a conspicuous example. It would be safe to assume that many of those who begrudged to pay sixpence a week to secure compensation in case of accident, would freely spend twice or thrice that amount at the saloonist's or tobacconist's counter.

THE organization of the Toronto Builders' Exchange on the lines of the Exchanges affiliated with the National Association of Builders of the United States, seems likely to mark a new and better era in the history of building in that city. For years there existed the Federated Association of Builders, but having been unsuitably planned, it accomplished but little in the direction of uniting and advancing the interests of the various trades. In the new organization the weak points in the old have been carefully avoided. The officers are known to be energetic and deeply enthusiastic in the success of the undertaking. A large membership has already been secured. Under these circumstances the success of the movement seems to be assured. Some of the objects of the Exchange as well as some of the benefits which it is in a position to confer upon its members are touched upon in an article which we print elsewhere in this paper. It has clearly defined purposes, and will no doubt succeed in placing on a more satisfactory footing the interests of its members. Already we learn that communications have been received from Ottawa and other cities desirous of establishing similar Exchanges. It is to be hoped that the movement will extend until every city of importance in the Dominion has its Exchange. When that stage shall have been reached, the next step should be the organization of a National Association representing the various Exchanges and the building interests of the whole country.

THE attention of the Government has been called to the fact that the contractor for the new Toronto drill hall is having the cut stone work done in the Province of Quebec, thus depriving local workmen of the employment to which they deem themselves to be entitled. It does appear to us, as we have before stated, that the city of Toronto having provided the Government with a free site for the building, might reasonably expect that employment would be given to local workmen who must bear their share of the taxes imposed by the purchase of the land. At the same time the city and the Government both having failed to make this a condition either of the agreement between the city and the Government or the Government and the contractor, it is too much to expect that anything can now be done to remedy the matter. The contractor in making up his tender had in view the employment of Quebec labor, as a result of which it is claimed he will effect a saving of about $40,000. Having obtained the contract without restrictions, his right to carry it out by whatever means will yield him the greatest amount of profit, cannot be fairly called in question. Whatever fault may be found belongs to the City Council which neglected in the negotiations with the Government, to protect the interests of the local workmen.

SINCE our last issue the examinations of the candidates for admission as members of the Ontario Association of Architects, have taken place, but they were billed too late in the month for us to obtain any report as to results that we could use in this issue; we hope to be able to give full particulars next month. In the meantime we may say that by permission of the Minister of Education, the Hon. G. W. Ross, and Professor Galbraith, (who is also Chairman of the Board of Examiners), the examinations were held in the examination hall at the School of Practical Science, where in profound peace and quiet thirty-five candidates spent three hours twice a day for four days working at the papers set. The Moderators were members of the Board of Examiners, and two or three were present at each examination to order the routine and supervise. The Board of Examiners consists of Professor Galbraith, Chairman; Mr. Wright, Lecturer in Architecture of the school, and the following architects: Messrs. Burke, Gambier-Bousfield, Curry, (President of the O. A. A.), Darling and Townsend. We understand that the results will be made known as soon as possible, but it must necessarily take some time for the Board as a whole to consider the reports of each of its members and finally to decide who have passed and who have not. The candidates at these examinations, whether successful or not, will carry away with them a lesson that will serve them all their lives, so that none need think he has wasted four good days. An examination in any subject is an excellent education; it has often the effect of an "eye opener," and there are but few upon whom such a tonic does not work beneficially.

NO arrangement has yet been arrived at concerning the method to be used for propelling the electric cars of the Toronto street railway. The question is between the "trolley" system and the "storage" system; the one has about as many supporters as the other, and therefore it is difficult to come to a decision. As a matter of fact the "storage" system is in its infancy only, and, though in a few years time it may be developed with practical utility, yet at present its adoption would only be a most costly experiment and probably fraught with a good deal of danger. The "trolley" system has been tried and found practically useful in many places, and, though by no means a perfect arrangement, is undoubtedly the best, if indeed it is not the only one possible under the circumstances for introduction to Toronto. A contemporary speaks of it as "the most uncivilized convenience known to our times," and certainly it is not a desirable system were there any better to choose from, but is at present "Hobson's choice." In the meantime, while this matter remains unsettled, the streets remain in the worst possible condition. New permanent roadways have been promised for the last three or four years, yet it looks as if it will be another season before we shall see any improvement. The change of system for the street cars, from horses to electricity means an entire change of the roadbeds over which the lines are to run. Not only have our aldermen not decided about the paving, but it is by no means certain which streets the cars will run along. It is proposed to make a single line running west on one street, and a return single line running east on an adjacent parallel street wherever such an arrangement can be carried out. When these points will be settled nobody can possibly tell. At the present rate of progress it may possibly be a couple of years or more.

OUR ILLUSTRATIONS.

PHOTOGRAVURE PLATE—RESIDENCE OF MR. W. H. A. MASSEY, JARVIS STREET, TORONTO—WM. YOUNG, ARCHITECT, NEW YORK.

RESIDENCE OF MR. HECTOR MCKENZIE, MONTREAL.—J. W. & E. C. HOPKINS, ARCHITECTS, MONTREAL.

The stone is imported freestone of a most pleasing color from the "Mowat Quarries," Scotland, supplied through Thos. Samuel & Sons, Canadian agents, Montreal and Toronto.

ONTARIO SOCIETY OF ARTISTS.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—The next annual exhibition of this society will be opened on May the 23rd next, in their Art Gallery, 175 King street W., Toronto. Pictures, perspectives, drawings etc., must be delivered unpacked at gallery not later than May 17th. The title of pictures, with name and address of architect to be on the back of each frame. All work must be sent at owner's risk, but an insurance during exhibition will be effected by the society. It is proposed to issue an illustrated catalogue, and to make it a success, it is necessary to have each architect represented. The size of sketches should 2⅞" x 4" or 4" x 6⅝", executed on lithographic transfer paper, grained, smooth or stippled, drawn in tuche or crayon. If unable to work in these mediums, photos to sizes may be substituted (accompanied with $2.50 to the Committee) and they will be drawn for the exhibitor by competent artists. Sketches, photos, drawings and communications should be sent to J. A. Radford, Adelaide street E., Toronto, not later than April 24th. Entry forms to be had of the Registrar of the Ontario Association of Architects, W. A. Langton, Merchant's Bank building, Toronto, and from Mr. Clift, Secretary of the Province of Quebec Association of Architects, St. James street, Montreal.

GRANITE ARCHITECTURE.

It may be useful to note that in modern granite architecture, as in the true granite style of the ancient Egyptians, simplicity in design should be a *sine qua non*. Such a treatment gives the most pleasing effect, says the *New York Manufacturer and Builder*, and is in perfect accordance with the hard nature of the material. Any attempt at elaboration is altogether out of place. Over-wrought granite is always painful to the sensitive eye, influenced, no doubt, by the remembrance of the vast amount of labor involved in the work. Over-polishing, too, has a peculiarly harsh and repulsive appearance, especially in the Aberdeen variety. A better and more pleasing effect may be obtained by employing a breadth of unpolished surface to heighten the value of the highly polished portions.

The House Committee on Public Buildings and Grounds at Washington, D. C., devoted four hours on the 10th ult., to hearing a committee of the American Institute of Architects upon House Bill 261, which is intended to change the practice of the Government in connection with the design and supervision of public buildings by turning the same over to the best architects of the country selected for each building with special references to its peculiar conditions and needs. It was asserted that by this means the standard of design and construction of Government buildings can be greatly improved. The Committee of Architects and the House Committee seemed to agree upon all essential points.

"ONLY THE HARDWARE."

It is always instructive to examine completed works of magnitude critically, and not only to admire but also to discover whether they might have been improved, as well as to profit by the experience thus gained for future work.

Such criticism is instructive for all branches of work, and in none is it more so than in the many new buildings which are constantly being erected in our great cities.

Among these is a new and beautiful hotel building worthy of highest admiration and praise for the effective manner in which the architect has designed the structure, and also included in one consistent whole the interior decoration. The various rooms are beautifully and brilliantly finished and the Renaissance school, after which the building is designed, lends itself admirably to the application of the most elaborate and effective ornamentation. In some portions the work merges into the latter developments of the Renaissance, and Rococco decoration and the work of the First Empire is freely used.

It is unfortunate, however, that in the midst of such effective work one item should have been so neglected as to mar the completeness of the work, and by its unsuitability cause a feeling of regret when it meets the eye. The hardware, which might have given such valuable aid in the completion of the scheme of decoration, appears to have no connection with the rest of the work, and it almost seems to have been chosen without regard to any of surroundings. Although used in connection with such elaborate work, and that, too, of a period in which the most beautiful designs in metal were made, we notice only plain bronze hardware, of the barest brand colonial outlines, conspicuous only by its incongruous appearance in the midst of so much that is brilliant and consistent.

One of the most beautiful portions of the building is the main reception room, which is in the Empire style, and the detail of which has been considered with extreme care, even to the extent of the small pieces of ornament applied to the doors, while below on the same door, where so much care has been expended in carrying out the details of the style, the unfortunate hardware to which reference has been made is shown in all its ugliness, particularly as it is of plain polished bronze, while the color of the woodwork is of a cream, which is so frequently used in this style of decoration.

It is the old story: "Only the hardware," and so not worthy of notice or care by the architect or decorator, and not until the work is done and it is too late to be considered does the magnitude of the error become apparent. The time is rapidly approaching, however, when the sadly neglected item is to be wholly redeemed from its present indefinable position, and by its growing importance demand the recognition which has so long been withheld.—*Trefoil.*

The following officers have been elected by the National Art Association for 1892 and 1893: Patron His Excellency, Lord Stanley; Honorary Patron, the Marquis of Lansdowne; President, O. B. Jacobi, Toronto; Vice-President, A. C. Hutchison, Montreal; Secretary-Treasurer, James Smith; Council, S. W. Watts, Ottawa; Forshaw, Ray, Kingston; A. F. Dunlop, Montreal; A. D. Taylor, Montreal; Hamilton McCarthy, Toronto; Thos. Fuller, Ottawa; Homes Watson, Doon; Mr. Matthews, Toronto; J. C. Hopkins, Montreal; Henry Labgley, Toronto; W. Brymner, Montreal, and Jos. Connolly, Toronto.

PERSONAL.

Mr. Fred. W. Farncomb has been admitted to partnership in the firm of Jones & McBride, architects, London, Ont.

We are pleased to learn that the Hon. C. F. Fraser, Minister of Public Works for Ontario, has been much improved in health by a sojourn of five months in Colorado. He is just returned home.

Mr. Murray A. White, Secretary of the Toronto Architectural Sketch Club, has removed to Chicago, having we are pleased to learn secured a position with a leading architectural firm of that city.

The firm of Daoust and Gendron, architects, Montreal, has been dissolved by mutual consent. Each member has opened an office in the city, and will continue to practice his profession on his own account.

PUBLICATIONS.

We are under obligation to the Secretary of the National Association of Builders of the United States, for a copy of the official report of the Sixth Annual Convention held at Cleveland in January last; also for a separately bound copy of the President's address.

SANITATION AND HEATING

SANITARY PLUMBING.*

By Cesare L. Marani, Grad. S. P. S.

Before we consider its proper construction and the disposition of its waste, permit me to say that the subject of "House Plumbing" has grown enormously within the last few years, and that now it holds a place of no small importance in the planning of buildings. For this reason it is impossible for me to do otherwise than to touch on such points as I consider of greater importance, and which, I fear, are often overlooked by the owner and architect.

Now that an increased desire for thorough sanitation is being manifested by the better classes, the sanitary engineer is often called upon, if not actually to take charge of the plumbing work, at least to plan and advise in the interests of health and economy.

At present this work is largely controlled by the architect and plumber combined, who seem more eager to attain to better results, and much more

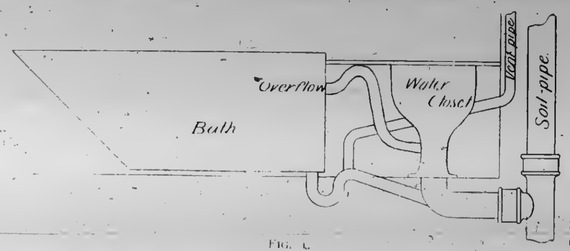

Fig. 1.

competent to do so, than they were formerly. Still it cannot be denied that the average architect possesses little or no scientific knowledge whatever on this important subject, thus clearly demonstrating a fact, that he and the rest of his profession attach too little importance to their responsibilities in connection with the plumbing of buildings, and therefore do not seem to experience for this that feeling of personal accountability so essential to success, which they do for other and less important sections of their work.

It is hardly necessary to explain that in these, and the remarks I am about to make, I refer not to the average members of "associations of architects," such as we now have in the Provinces of Ontario and Quebec, nor to the Boston Architectural Club, and other Societies in the States; but to the *average*, when we include all who may be said to be practising as architects, whether considered qualified to so by these architectural bodies or not, and therefore, in this way considering the *actual* centre of gravity that affects the general public.

Col. George E. Waring, writing on this subject for the information of architects, as well as others, goes on to say: "I have never applied a water test, under pressure, to work that has been done in a fine house under control of an architect, with any other result, so far as his frame of mind was concerned, than to annoy him by the demonstration of leaks and defects

"What seems still more remarkable, when I have sometimes thought that I had an architect really converted, when he acknowledged the work to be simple, elegant, safe, cheap, and in every way satisfactory, was that the conversion never lasted. I never found that the example had the slightest influence on him afterwards."

Sometimes we meet with owners, who, while they show all eagerness to consider from a standpoint of comfort, any proposed piece of plumbing work in connection with their house, nevertheless seem afraid to look on the sanitary aspect of the thing, lest the necessity of adopting certain changes or precautionary measures, might rise perforce before them, like the unwelcome ghost of Banquo. In the first place, any additional expense thus entailed, proving little or no obstacle; while in the second, the smallest outlay for the protection of health, would be regarded as a *dead loss*, and objected to in every possible way.

That an architect should ever pander to the wishes of such people, who may be said to be pursuing an ostrich-like policy, is indeed to be regretted.

Sometimes an owner imagines that his rights as Despot in his own castle are being encroached upon. It is then the duty of the architect to point out the wisdom of providing for the preservation of health and happiness, not only of himself, but also of others, since we are creatures very much dependent on our neighbors for our sanitary condition.

I knew an architect once who tried to exonerate himself from all responsibility in connection with a certain piece of "plumbing work," by saying that he had persuaded the owner to employ the best *practical plumbers* in town to do the said work, and that therefore there could be nothing wrong with it.

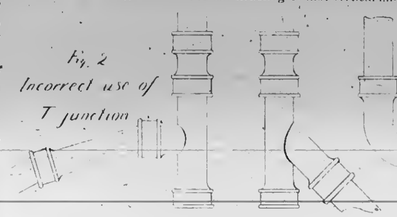
Obviously the above reasoning was rather sophistical. Who constitute the "best practical plumbers" in a community? Are they men of science as well as clever mechanics? Are they fully entitled, by a sound experience and careful study of their trade, to the full import of such an appellation? I fear not, and certainly much less to that signification which a too confiding public is ever sure to place on such titles. It is a fallacy to imagine that the knowledge of how to handle, cut, and connect pipes, wipe joints, and charge well, of necessity makes a man master of the plumber's trade. And yet I know, from experience, that in the great majority of cases, this is regarded as the criterion. It might seem that the impression prevails among a large class of pipe fitters and mechanics, that the possession of a certain number of working tools, together with the *valuable* assistance of a couple of incompetent "shop-boys," a large shingle suspended over the sidewalk, more pronounced in its economy for truth than expense, a few cast iron connections displayed just outside the shop, and lots of gas brackets and other brass fixtures inside, constitutes a man at once a "practical plumber." There are a great many good workmen who are by no means good plumbers, and still a great number of good plumbers who are by no means "Practical Plumbers and Sanitary Engineers," as they often style themselves.

It therefore falls back on the architect to provide the soul, yes, the ethereal spirit of theoretical knowledge, and furthermore, to see the same properly and practically incorporated in the work of the plumber. That a man can pursue the plumbing trade without having first thoroughly mastered it in all its details, I consider as the great present evil. Hundreds of dollars have been spent, to my knowledge, in rectifying blunders made by such workmen, of whom it might be said, and this justly, that they had come by their trade dishonestly, because by too short a route. They of course little cared what might befall to their work, much less to the health and happiness of others, so long as they might pocket their gains and remain in blissful oblivion as to their moral responsibilities. As an illustration, of what I should term downright practical ignorance, I might give a case that occurred in the town of Brockville, Ont., a few years ago.

One of the so-called "master plumbers," who, previous to his settlement in the town, had worked at his trade for nearly fifteen years in the city of Montreal, and who was therefore looked upon by the simple public as a most desirable man to employ, actually presented a piece of "plumbing work" to be passed and approved of by the Inspector, where a two inch lead pipe, two feet four inches in length, had been bent and used under the closet seat, so as to act as a vent pipe to the closet trap, and at the same time as an overflow, waste for the bath tub (see fig. 1). The workmanship, however, was simply perfect.

Not very long ago a case came under my notice in this city, where a long vertical line of soil pipes had choked and blocked up completely. It was thought at first that the servants must have thrown bones and rags, etc., down the closets, but further examination showed that there was nothing in the pipes, save the legitimate house wastes and closet paper.

The plumbers, in erecting the said line of pipes, had used too little gasket in some of the joints, and none at all in others. The consequence was, that the lead intended for the joints had spurted inside, and in some cases forming regular groups of fingers across the pipes, thus obstructing the passage of paper, etc. The only way this could be rectified was by the tearing down and re-constructing of that vertical line of soil pipes.



On investigation, it was found that the plumber, who was responsible for this, had had no intention of scamping his work. He had made some extraordinary experiments (by himself), which had convinced him against using a gasket where he could possibly help it. He had come to the conclusion that though a gasket was of great assistance in preventing any loss of lead while pouring a joint, yet from a sanitary standpoint it was objectionable as absorbing and retaining filthy liquids. In the interests of his employers therefore, he had decided to use gasketing only where it was impossible to do without it, and the good faith of the man was manifested in that he had not charged for gasketing, nor for the amount of extra lead he must have lost in trying to fill the joints. It is needless to explain further.

To my mind the house is the unit of sanitary administration. In fact, the whole sewerage system beyond, with its many intricacies and problems, both mechanical and financial, never would have developed, nor even have sprung into existence, but for the dwelling.

We may look upon man's modern habitation, therefore, as the principal source from whence all sewerage estimates. To secure perfect safety to the inmates, while removing at the same time the daily household wastes beyond the outer walls, is then our first consideration. Except where houses are

* Lecture delivered before the Engineering Society of the School of Practical Science, Toronto.

isolated, or strung out in small colonies along concession roads, or again clustered into hamlets and villages, what is known as the water carriage system is by far the most efficacious for the removal of the daily semi-liquid and liquid wastes of the dwelling. By wastes, I mean human excreta, chamber slops, water used for baths, water in which dishes, pots, vegetables, clothes, etc., have been washed, and in fact any water that has been put to a thousand and one of its other uses in a house. We might consider the following as our "plumbing" axioms, and the system with its fixtures, traps, ventilation, and waste pipes, etc., that will conform in the highest degree to them, must perforce be accepted as the best. It is then evident:

Firstly.—That the waste matters generated in the house should be removed at once.

Secondly.—That so far as it lies in our power, the waste pipe system should be freed from any tendency to retain decomposing matter giving off gaseous products known to be detrimental to health, or these very gases when generated elsewhere.

Thirdly.—That every part of the plumbing should be visible where possible, and conveniently situated as against repairs or accidents.

Fourthly.—That all parts should be of sound materials free from flaws, blemishes, or other defects, and of the kind of material best suited for their special purposes.

Fifthly.—That the whole system should be put tightly together, in the best approved manner, and possessing uniformity in strength and durability.

Sixthly.—That the whole system should be as simple as possible, consistent with convenience, efficiency, and security.

Seventhly.—That the appliances used should be economical, reliable, and adding materially to the comforts of the inmates of the building.

That the waste matters generated in the house be removed at once, can be attained by having as direct and short a line of waste and soil pipes as possible. Every necessary bend in a line of pipes being made by a regular curve, and never abruptly. Wherever the waste and soil pipes run otherwise than vertically, ample grades should be provided. The smoothness and evenness of the interior of the pipes, along with their size, and also the manner in which they are connected and branched together, having a marked effect on the velocity of discharge.

The use of an inverted T or Y junction for the purpose of effecting a connection between a vertical and horizontal line of pipes, should never be tolerated. The reasons are obvious (see figs. 2, 3). I have actually come across several cases of this unscientific mode of construction.

As there seems to exist, even among writers on sanitation, an uncertainty as to the exact meaning of the terms *house drain*, *soil pipes*, *waste pipes*, etc., it might not be out of place for us to decide upon their proper application before proceeding further. Let a house be given us, and a hundred feet away the street sewer. (See fig. 4).

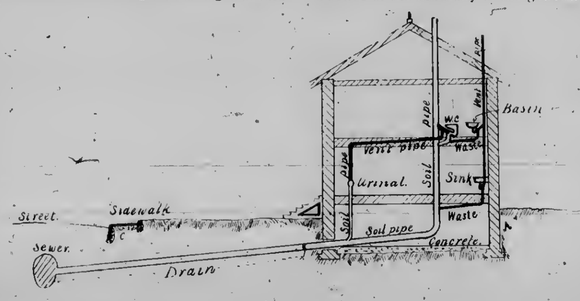


Fig. 4.

Then the system of pipes commencing at the street sewer, running up to the walls of the house, passing through them, and then branching out throughout the building, may be divided into two parts. First, that part outside the street sewer and the outer walls; and secondly, that part inside the dwelling. The first is known as the *house drain*, or *drain*, and conveys to the said street sewer all liquids and semi-liquid wastes, and further, all roof and cellar water that may be trapped into it.

The second part, inside the dwelling, is again sub-divided into *soil pipes*, *waste pipes*, and *vent pipes*.

Soil pipes, or soil pipes, are those pipes which carry away human excreta, principally from water-closets, and form the main trunks of the plumbing system of buildings. As such, therefore, they almost invariably receive in addition, the wastes from baths, basins, sinks, tubs, etc., that are conveyed to them by the waste pipes of the system.

Laterals to the main trunks, receiving liquid excreta from hoppers and urinals, are called soil pipes only in a secondary sense, while vent pipes form that part of the system which does not convey waste waters or sewerage of any kind, but is intended to afford free ventilation to the different parts, and to the syphoning of traps. Such portion of the soil pipe as may be found above the highest fixtures, however, and there for no other purpose than that of ventilation, curiously enough retains the name of soil pipe, and does not come under the classification of vent pipes.

We therefore have waste pipes in connection with all fixtures, save those into which human excreta may be emptied. These waste pipes may either enter the house drain independently, or join the soil pipe and discharge their liquid wastes into it.

Soil pipes again may convey excreta alone, or all the wastes of the house to the drain beyond the walls, while at the same time acting as the main ventilating shafts of the system, since their upper ends are always left open and carried well above the roof.

Lastly, the house drain, or simply drain, conveys to the sewer all liquid and semi-liquid wastes placed beyond the walls of the building by the soil and waste pipes.

It must be understood that we have simply considered these terms as applied to house plumbing, and house drains, and not as in the subject of land drainage, nor as in certain of the distinctions used in what is known as the "Separate System of Sewerage."

(To be Continued.)

HOW TO SELECT A SITE FOR A COUNTRY HOUSE.

There are no definite rules, of course, that will always apply to the selection of a site for the house. Usually it should not be placed exactly in the middle of a place, or close to the front, and it should associate itself in some way with some considerable plantation of trees that may already exist.

I am speaking of considerations that must be met in a systematic way, and more or less in accordance with the best practice of the art of landscape gardening. But avoid being too conventionally artistic. Use common sense, and first of all make your grounds comfortable and convenient; then do what you can for the æsthetic. The latter may, in your opinion, be of the most importance, but the former, be sure, will, sooner or later, revenge itself upon you for any undue neglect.

I am speaking now of all country places, meaning thereby a lot that may be only 25 feet by 100 feet, or may be five or six acres. In any case you are devising a picture when you undertake to lay out your grounds, even in the most simple fashion; and any arrangement that will develop and present with the best effect the most artistically valuable features, should be invariably chosen, though at first it may seem odd, and not in accordance with your conventional ideas of landscape gardening art. Any evident attempt at mere oddity is, of course, bad, and destructive of the harmony of the general arrangement; but there may be an unusualness of treatment that *seems* odd, though in reality effective and harmonious, simply because it is conventional.

Against one thing let me warn the reader, and that is the indiscriminate use of formal foliage or flower-beds on most lawns. They are apt to lend a garish and vulgar air to the place. Close to the house you may sometimes use one or two of these beds, but their bright red and yellow colors should be set a little on one side and not allowed to glare at one too much. I respect the universal delight in rich color, but all formal patches of color should be used carefully and in proper relations to the whole picture.—Samuel Parsons, Jr., Supt. of Parks, New York, in March *Scribner*.

POINTS ABOUT ADVERTISING.

John Wanamaker, who can claim to speak from experience says: "I never in my life used such a thing as a poster or dodger, or handbill. My plan for fifteen years has been to buy so much space in the newspaper and fill it up with what I wanted. I would not give an advertisement in a newspaper of 500 circulation for 5,000 dodgers or posters. If I wanted to sell cheap jewelry or run a gambling scheme I might use posters, but I would not insult a decent reading public with handbills. The class of people who read such things are poor material to look to for support in mercantile affairs. I deal directly with the publisher. I say to him 'How long will you let me run a column of matter through your paper for $100 or $500?' as the case may be. I let him do the figuring, and if I think he is not trying to take more than his share I give him the copy. I lay aside the profits on a particular line of goods for advertising purposes. The first year I laid aside $3,000; last year I laid aside and spent $40,000. I have done better this year and shall increase that sum as the profits warrant it. I owe my success to the newspapers."

Mr. King Arnoldi, of Ottawa, recently secured judgment against the School Board of Vankleek Hill, Ont., for the amount of his fees for preparing plans for the new school at that place.

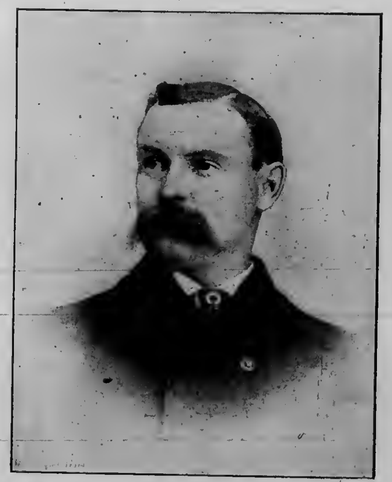
TORONTO BUILDERS' EXCHANGE.

We have much pleasure in presenting to readers of the Canadian Architect and Builder the portrait of Mr. Wm. J. Hill, the President of the newly organized Builders' Exchange of Toronto, accompanied by a few particulars concerning the organization. The other officers are: Geo. Moir, 1st Vice-President; Geo. Oakley, 2nd Vice-President; David Williams, Treasurer; John Aldridge, Benjamin Brick, William Park, James Crang, M. Murphy, J. L. Nichols, Directors.

The Exchange owes its existence to the fact that the Federated Association of Builders and Contractors, which it supersedes, was not fulfilling the objects it was designed to serve, and certain members determined no longer to be satisfied with its inefficiency, but to establish a new organization founded on the lines of the Builders' Exchanges represented by the National Association of Builders of the United States, whose operation has proved to be most beneficial and satisfactory. The formation of the old Association was such that it was almost impossible to secure concerted action on any question. It was composed of an equal number of delegates from the different trades, and was designed to be maintained by the imposition of a capitation tax. Being thus made up of a number of independent bodies, there was the tendency to narrowness and sectionalism when occasion called for broad and liberal measures. The organization was necessarily unwieldly and lacked cohesiveness.

In 1891 some energetic members of the Master Masons' Section, as has been stated, tired of the organization and withdrew from it, with the object of instituting something better. A sufficient list of signatures was easily obtained to enable application to be made for a charter, which was granted, the provisional Board of Directors consisting of Messrs. G. Wright, M. Murphy, J. Crang, J. Aldridge, W. Williams, B. Brick and J. Nichols.

A code of by-laws was drawn up, and a book of certificates of membership printed, and although scarcely two months have elapsed since its formation, we are informed that fully 80 per cent. of the builders and contractors of the city have become connected with the organization, which may be regarded as a sufficient justification of the wisdom of the promoters of the undertaking.



Mr. W. J. Hill, President Toronto Builders' Exchange.

The membership is divided into two classes, designated as "corporate" and "non-corporate" members. The former includes all persons actively engaged as building contractors, and the latter, manufacturers and dealers in building materials. "Non-corporate" members enjoy all the privileges of the Exchange, except that of voting. The fees are the same for both classes, viz., $10 per year, and in the case of new members, an additional entrance fee of $10.

Applications for membership should be made to the Secretary. The name of every applicant is posted for one week on the walls of the Exchange, at the end of which time if no objection is made the application is dealt with by the Board of Directors. The control of the Exchange is vested in a Board of Directors, who must hold corporate certificates. The Exchange has power to form sections to represent the various branches of the building trades and promote their special interests.

Arrangements are being made with dealers for a trade discount to be given to members who may pay their accounts before the 10th of each month. These discounts will be more than sufficient to cover the cost of membership. By this means also an effort is to be made to discourage the credit system which has to so large an extent demoralized the building business.

Any disputes which may arise between members of the Exchange will be adjusted by means of arbitration. Under the by-laws no member is allowed to bring suit in the courts against another with whom he may have a difference, until every means of settling the difficulty by means of arbitration has been exhausted. Instead of appointing an arbitration committee, the whole Exchange has been constituted a committee of arbitration, so that members desiring the services of arbitrators are at liberty to select from the entire membership persons in whose judgment they may have the most confidence. In this direction the Exchange is likely to be the means of saving its members a large amount of money which would otherwise be spent in litigation. An instance comes to mind of a dispute of a somewhat trifling nature between a contractor and sub-contractor, the settlement of which by the courts cost the litigants seven hundred dollars. Such cases are not unusual, yet it would no doubt be found possible under the method adopted by the Exchange to bring about a settlement of the greater part of them at a trifling cost. Members desirous of having their claims arbitrated upon will be required to make a deposit sufficient to cover the cost. In this connection it may be mentioned that as members of an incorporated body, members of the Exchange who may in future be called upon to give expert evidence as witnesses in building cases, will be entitled to receive $5 per day for their services, instead of as heretofore, getting $1.00 per day as though their testimony was of no greater value than that of the laborer who might be asked to substantiate the simplest fact.

The Exchange has appointed a Legislation Committee to provide for the improvement of the form of contract, and laws affecting the building trade; a Committee to provide for improved arrangements between the contractor and the architect with regard to the method of issuing certificates, etc., and a Labor Committee to secure better arrangements as to wages and other matters affecting the relationship of employers and employees.

The new Exchange has started out honorably by paying off all moral and legal liabilities of the old Association. It starts out without any entanglements or old agreements, and will refrain from making any agreements until certain objectionable conditions which at present prevail shall have been remedied.

In concluding this reference to the new Exchange, which seems designed to have a most successful career, we reprint from a copy which has come into our hands the "Stipulations of the Toronto General Builders' Society," bearing date February, 1867, together with the names of the members representing the various trades, many of whom still occupy positions of prominence and public esteem:

1. Detail drawings to be furnished by the architect at the time of tendering.

2. Contractors to attend at the required time, and be present at the opening of tenders.

3. The lowest tender to be accepted, and if not accepted or work not proceeded with, such tenderer to be remunerated at the rate of one-half per cent. on new work, or one per cent. on alterations and repairs, for time, trouble and expense in preparing such tenders.

4. Work not mentioned in the specifications, or shewn on the drawings at the time of tendering, to be paid for as extra work.

5. The owner of the property to execute the contract in duplicate, and sign plans and specifications, at the same time as the contractor, and one duplicate original, so executed, to be delivered to contractor.

6. The contractor to be paid as the work progresses, at the rate of eighty-five per cent. on work done and materials furnished including extra work.

7. The contractor to have a lien on the building or other erection for unpaid contract money, and the right, if so disposed, to withhold possession until the contract money, or such portion thereof as he may be entitled to at the time of the completion of the work, be paid.

8. The work, as it progresses, to be kept insured in some responible insurance office, in the name either of the owner or contractor, and such insurance to be for the joint benefit of both in the proportions in which they are respectively interested; and the premium, if paid by the contractor, to be added by him to the amount of his contract.

9. In the event of a dispute or disputes between the owner or architect, and contractor, the contractor to be allowed to appoint an arbitrator, who, with the architect, shall decide the matter in dispute; and in the event of their failing to do so, they shall appoint a third arbitrator, and the decision of the three, or majority of them, shall be final.

10. All alterations or additions to contract to be only proceeded with on the written order of architect or proprietor.

The undersigned agree with each other, well and truly to observe the stipulations annexed, in all respects according to their true intent and meaning, and not in any manner to act contrary thereto, or accept any contract in violation of the same, or at variance therewith:

Masons and Bricklayers—Scott & Stolley, Ramsay & Farquhar, Edward Synge, Thomas Snarr, Joseph Gearing, Edward Galley, Robert Carrol Jr., W. J. Hughes, W. H. Booth, William Ireson, May & Gibbins, John W. Bowden, John Platt,

Stone Cutters—Scott & Stolley, Ramsay Farquhar, Edward Synge.

Carpenters and Joiners—William Burke, Jacob P. Wagner, Withrow & Hillock, Robbins & Worth, James McBean, William Moulds, John Shanklin, William Latch, John Wilson, J. W. Phillips, John Plenderleith, Robert Kennedy, Ford & Forbes, Fowler & Coleman, William Briggs, William Horton, Mark Hall, John Oliver, Peter A. Scott, James Farley, George Emery, John Greenlees.

Painters and Glaziers—G. Pearcy & Son, Dill & Milligan, William Stanley, George Booth, Andrew Widdowson, James Thomson, William Fry, Robert Bell, William Elliott, Joseph McCausland, John Bilton, John Kidd, W. D. Rogers

Plumbers, &c.—John Ritchie, Cummings & Wells.

Plasterers—Joseph Gibson, Thomas Jennings, Joseph Gearing, Thomas Snarr.

OBITUARY.

With sincere regret we have this month to record the decease of a very worthy gentleman who for the past 17 years has been a well known figure in the city of Montreal. Mr. J. C. Radford for all this period was Health Officer in that city, and probably no civic official was better known among architects and builders. He was universally respected and his remains were followed to the grave by the City Council, the Board of Health and many with whom in life, in the excerise of his functions he had continually to do. He was a Trustee of the First Baptist Church and the President of the Temperance Society.

MONTREAL

(Correspondence of the Canadian Architect and Builder.)

I regret to have to state that Mr. P. W. St. George, City Surveyor, has been confined to his residence for some weeks by a severe illness. Happily however, he is now on the road to convalescence, and on the advice of his physician will spend a short time in the South. It is hoped that he will shortly return home fully restored to health.

Mr. McConnell, Superintendent of the City Water Works Department, has resigned his position owing to inability to work harmoniously with the water committee. Mr. McConnell was a valuable official, and his retirement is therefore to be regretted.

Plans have been prepared and submitted to the President of the Grand Trunk Railway Company, for the extension of Victoria Bridge, with the object of providing a grand promenade for vehicle and pedestrian traffic across the river.

An old and highly esteemed civic employé has passed away in the person of the late Mr. Glackmeyer, City Clerk. For nearly a half century the deceased gentleman satisfactorily served the city, and his removal is the subject of the deepest regret to past and present members of the Council as well as a wide circle of acquaintances among all classes of the community.

Following is a list of the members of the Province of Quebec Association of Architects registered up to the close of 1891:

C. T. Ballard, J. H. Bowe, L. J. Browne, R. P. Barnes, Chs. Chausse, Chris. Clift, Theo. Daoust, W. E. Doran, J. E. Doré, A. F. Dunlop, A. Dubreuil, John Esinhart, Robert Findlay, A. Flockton, A. G. Fowler, J. R. Gardner, L. Z. Gauthier, A. Gendron, Jos. Haynes, W. H. Hodson, E. C. Hopkins, J. W. Hopkins, A. C. Hutchison, A. H. Lapierre, G. De G. Languedoc, S. Lesage, A. Levreque, O. Mailloux, E. Mann, E. Maxwell, L. R. Montbriant, James Nelson, H. C. Nelson, Jos. Perrault, H. M. Perrault, M. Perrault, A. Préfontaine, A. Raza, J. B. Resther, J. Z. Resther, J. D. Rhind, Victor Roy, J. Simard, James Smith, C. St. Jean, A. T. Taylor, W. T. Thomas, Jos. Veene, A. Vincent, W. McLea Walbank, Geo. W. Wood, James Wright, W. S. Wright, Montreal.

Chs. Baillairgé, F. X. Berlinquet, J. B. Bertrand, J. George Bussières, Chs. Bernier, D. Ouellett, L. C. Ernest Pagé, J. F. Peachy, Thos. Raymond, Harry Staveley, G. E. Tanguay, Alfred Vallée, Quebec.

A. Boileau, St. Genevieve (Jac.-Car.)

A. H. Larochelle, Lévis, P. Q.

E. M. Talbot, St. Roch, Que.

The Art Association's spring exhibition of paintings will open next week. The following list of prizes will be offered for competition at the exhibition:—For the best figure painting, in oil $200; second best $100; for the best sea or landscape $200; second best $100; for the best portrait $100; for the best painting of still life $100; for the best painting by an artist under thirty years of age, not a Royal Canadian academician or associate $100; second best $50. In addition to these a special prize of $200 will be awarded to the picture obtaining the greatest number of votes from visitors attending the exhibition, each ticket of admission carrying one vote. This competition is open to all pictures of Canadian artists without distinction, and can be won by the recipient of any other prize. It is hoped by this means to encourage a more thorough study and criticism of the pictures exhibited as well as to find out the direction of popular taste in art. It is in contemplation to make extensive additions to the Association building at a cost of about $35,000, by means of which the picture gallery will be doubled in size, and class rooms, studio and reading rooms provided. The work will be commenced on the 1st of May.

FROST: ITS EFFECTS ON BUILDING.

Out-of-door building operations have been much interfered with by the recent frosts. In many new houses which are being erected by the speculative builder the mortar-joints and pointing have become loose or disintegrated or entirely fallen out through the moisture in the materials. The unfortunate buyer who is persuaded to invest in house property may find a heavy outlay required in making good the brickwork, in repointing, in restoring stonework that has fractured and become loose by the wedge-like action of expansion incident to frost. We cannot understand any builder, except under pecuniary obligations, proceeding with brickwork during a severe frost. He generally takes not the slightest precaution to cover the walls with weather-boards or straw or to use quick-setting mortar made of unslacked lime, a practice which prevails at Christiania, and is said to be successful. This indifference aggravates the offence. Even in Christiania, where building in frosty weather has received particular attention, it is considered that bricklayers' work does not answer in more than 14 to 9½ below freezing point. The bricks too, lie exposed to all weathers on building estates; there is no attempt made to protect them from the rain or frost; the consequence is, they are used filled with moisture or congealed water. So with blocks of stone; we have seen them sawn and left exposed to the rain or snow, and immediately afterwards cut up and built up on the brickwork. No one looks after these irregularities, and they go on unchecked until the results are shown in rotten brickwork and stone that flies all to pieces.

In glazing roofs, the same indifference to weather is met with. As glass expands and contracts by heat and cold, the putty joints give way and crack. It is very seldom that we find ordinary care shown as in leaving room in the rebates for expansion and contraction of large sheets of glass, or, better still, to fixing the glass in grooves, especially for shop-front windows. Many systems of patent glazing, such as that of Helliwell, by affording protection to the joints by lead caps, and allowing grooves underneath for condensed moisture, prevent the mischief. The effects of severe frost tell more seriously on the work of the plumber. Not only do the pipes give way by the expansion of the water in them, but the lead flats and gutters contract to such an extent as to cause them to split or tear in the weak parts, or at their connections with the flashings. Yet it is extraordinary that the same unscientific method of laying and fixing should prevail, and that architects still permit these modes of execution to be carried out, or lead to be used unable to bear the strain put upon it. When we can insist on a certain thickness of lead for flats and gutters, and specify certain methods of laying to allow for contraction, when we can incase our water pipes and cover them in non-conducting substances, and provide taps for emptying them during a severe frost, when we can fix our pipes without holding them tight at the joints, there ought to be no possible excuse for allowing them to become exposed to the destructive agencies of frost and heat. The public hailed the advent of the "registered" plumber to do much to prevent these shortcomings, to instruct in scientific plumbing, and to create an improved system of sanitation; but all will be of no purpose unless the appreciative British employer puts within his reach the means for securing the benefits of technical skill, which he can only to do by putting his hand in his pocket and paying honestly those who can best do the work.

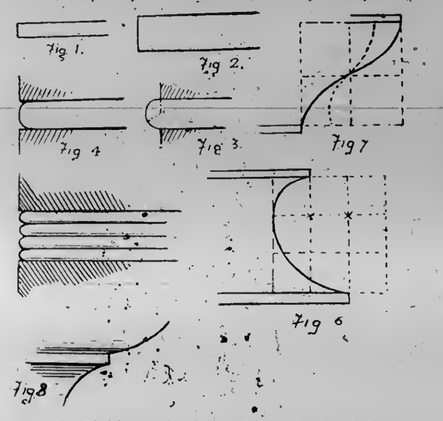
TORONTO ARCHITECTURAL SKETCH CLUB.

The members of the above Club will hold their second annual dinner at Webb's restaurant next Tuesday evening, the 19th inst. The occasion will afford an opportunity for recuperation to those who have been expending so much energy on the recent O. A. A. examinations.

DECORATION AND FURNITURE

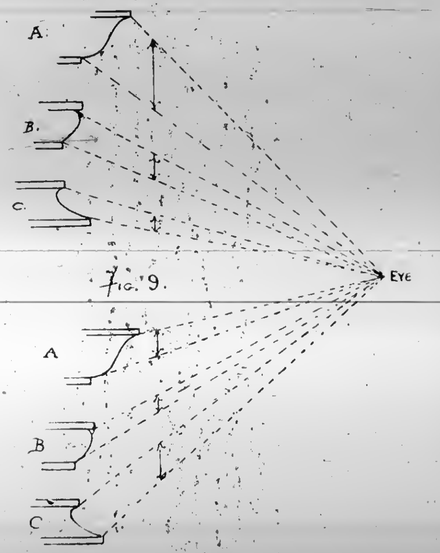
THE ARRANGEMENT OF MOULDINGS.

IN this article we purpose to show how mouldings should be arranged, according to the place and position they are to occupy. It is evident what an important part mouldings play by the fact of being employed in such different substances. They are used in woodwork, pottery, and stonework, also in jewellery, and are



perhaps the chief feature in picture frames, besides being represented in the flat by means of painted lines in such cases as the partitions on vases, painted panels on flat surfaces, etc., ; and wherever a space requires a border, it is often supplied by lines of different thicknesses and depths of space between them.

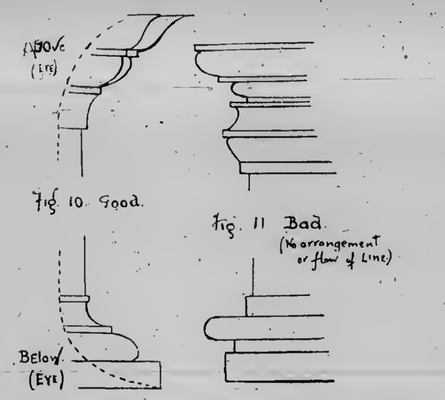
Let us look at a few positions that mouldings occupy in connection with the different substances in which they are employed. Mouldings are prominent in their use to woodwork with



regard to panelling, and are applied to emphasize the shape of the panels on which they are used. Whenever any size of somewhat large dimensions is required to be decorated and the space is too large to decorate directly it is usual to panel it up into good proportions by means of mouldings. Again, in buildings they break the monotony by being introduced at the various stages or stories. For inside decoration also, mouldings are used for the cornice, and at the bottom of the dado; in fact, almost everything we look at has mouldings. Cupboards, table legs, and window frames, although we may not have noticed them particularly, are all, more or less, composed of mouldings. If these objects had been plain, we should very soon have noticed the deficiency - hence the value of mouldings.

Figs. 1 to 8 show the various kinds and proportions of the mouldings which we are going to consider. The designing and arranging of all of them are based on these, and it would be as well to remember that each of these belong to one of the following four classes: flat, convex, concave, or compound. A *flat* moulding is one which neither projects nor recedes. A *convex* may be any shape (*i.e.*, degree of curvature), if it projects only. A *concave* moulding is one that recedes, no matter at what angle, whilst a *compound* moulding is the combination of a convex and a concave. It is the combination of these different kinds that we are now going to consider, as well as how they should be arranged.

The several names and positions of these are as follows: Fig. 1 is called a fillet; it is the smallest moulding, but perhaps the most important one, as it is used to connect one moulding with another. The Tenia (Fig. 2.) is really a large fillet, and forms the Abacus



in the Doric Order. The Astragal, shown in Fig. 3, is a convex moulding; its projection is half a circle. Fig. 4 is called a bead moulding, and is like Fig. 3 without the projection, whilst a number of bead mouldings placed together is called a reeding, as shown in Fig. 5.

The Scotia is a very fine example of a concave moulding; it recedes two-thirds its own height, and the method for obtaining it is shown in Fig. 6 by the dotted lines and xx, which mark the centres of the quarter circles. A compound moulding is the combination of a concave and convex (Fig. 7). It is often divided by a fillet (Fig. 8), which emphasizes the curve and makes effective lights and shadows. It is the difference of projection in these mouldings that makes it necessary to consider whether they should be placed above or below the eye. Fig 6, for example, shows repetitions of the same mouldings, but by comparing *a* above with *a* below, it will be seen that the top *a* makes a capital crowning piece in this position.

Flow of line is the chief consideration in arranging the different kinds of mouldings together, and Fig. 10 shows a much better arrangement than Fig. 11. The reason for this is on account of this flow of line shown by the dotted line, which only in the one case has been regarded.—"H. R. C." in *Furniture and Decoration.*

WINDOW GLASS IN ARCHITECTURE.

THE papers on "Painted Glass" which were read at the Institute two or three weeks ago would have been more in place, perhaps, at the Architectural Association. Good enough as far as they went, they did not go far enough to be of much service to practising architects. They told them what they knew already, and little besides. And this was not because the authors had little to tell—undoubtedly they could, under more favorable conditions, have said a great deal which would have been extremely valuable. But it so happened that most, if not all, of them selected subjects which might well have occupied a whole

evening, or several evenings; and yet were limited, in the length of their papers, to something which could be read in less than half an hour. The result was that, for the most part, they were occupied with the elementary facts of the matter. They skimmed over too large a surface, and had not time to go down to the treasures below.

Yet the treatment of painted glass, which was practically confined on this occasion to that of figure subjects, is only a small part of the question. It may be the highest part, but it is also, for most architects, the exceptional part. Every building, from the cheapest to the costliest, contains window glazing; and to many people it is constantly in view through a great part of the day. How to improve "domestic" glass is, therefore, for most of us a more intimate and pressing question than how to deal with the "storied windows, richly dight," of churches and monumental structures. We have outlived the time when a gigantic sheet of "British plate" satisfied the highest ambition of the British householder. We are in a period which is trying, like the olden ones, to apply art to common things. But though common things in brickwork and woodwork and metalwork are getting their share of attention, common things in glazing seem to be rather neglected. It is rare to find anything of this sort with a trace of art about it between elaborate stained glass and plain 21oz. sheet.

Then, again, the essential things which pertain to glass—which distinguish good glass from bad—are largely things relating to color and quality; to color and texture, if one may use the latter word for want of a better. Now, these are precisely the things which words cannot describe, and which diagrams cannot display. To make it clear which glass is excellent and which is execrable, the only way is to show the glass itself, and to show it by daylight. The difficulty is, that this can seldom be done at an evening lecture. Specimens can be handed round, but their real tints and tones when sunlight passes through them can hardly even be guessed at. And a passing glance at such specimens is not enough. They need to be stored where an architect can return and study them at leisure. They should, in short, form part of a permanent and easily accessible collection. It need be little more than a collection of samples. It is not figures of saints and angels that are wanted. It is a lot of pieces of glass of all kinds and colors, old and new. The old pieces should be marked with their date, or approximate date, and place of origin; and the new pieces with their makers' names. They would have to be fixed in leads, perhaps, for security; but there must be no labels requesting visitors "not to touch." The object is to afford facilities for getting to know them thoroughly, both by sight and feeling.

With such a museum of samples as this—a museum which, even if it occupied only one small and well lighted room, would be infinitely better than nothing, every architect would have it in his power to ascertain what glazing materials were actually available, and would be able to design his work accordingly. Of course, the scheme is not ambitious enough to attract the support of the nation or of the public. We are not likely to see it carried out at South Kensington, where the examples of old glass which exist are very inconveniently placed for study. But it would be well worth the while of any first-rate firm, concerned in the manufacture, to put together such a collection, and to throw it open to architects. It would bring more business than an illustrated catalogue, and at a fraction of the cost.—*Building News.*

We are glad to note that the day has come when the architect is beginning to appreciate the fact that the advertisers who place their business in the architectural journals are not alone advertising their goods, but making it possible for the architectural profession and building trades to be represented by the highest class and most expensive journals of the country. A few mornings since we were in the office of a prominent architect who upon opening his mail immediately consigned all the circulars, etc., to the waste basket, saying in explanation of his action that he paid about two hundred dollars a year for architectural periodicals and from these he expected to keep fully informed on all matters of interest in his business. Continuing he said: "I have little use for the firm that will seek to bore us with tons of this sort of advertising matter, and cannot see how they can expect a busy architect to wade through such a mass of stuff when he can by reference to his papers gain the desired information." As the busy architect is the only one who has use for any amount of building materials there can be no advantage in going to the great expense of reaching the man who has no better employment than the reading of circulars.—*Northwestern Architect.*

MANUFACTURES AND MATERIALS

HYDRAULIC CEMENTS—NATURAL AND ARTIFICIAL.*

THERE are two classes of hydraulic cements with which we are all familiar, the artificial, or so-called Portland, and that produced from natural cement rock. All hydraulic cements, whether artificial or natural, are produced by a mixture of clay and carbonate of lime, or lime and magnesia.

In the manufacture of Portland cement in England, the clay is mostly selected from the river beds and the carbonate of lime from the chalk deposits which form a large portion of England's surface, and is a nearly pure carbonate of lime. Limestone is used wherever the chalk is unobtainable in some parts of England and Germany, and elsewhere, and is finely pulverized preparatory to its mixture with clay. These two ingredients are usually mixed together in a pug mill, with a free use of water. Sometimes, however, they are ground together in a comparatively dry state.

The material as it enters the kiln, whether it be an artificial mixture or a natural cement stone, is a mechanical combination of two chemical compounds, *i. e.*, silicate of alumina and carbonate of lime. The preliminary operation in calcination is the expulsion of moisture, which is soon followed by the carbonic acid contained in the carbonate of lime. The Portland cement manufacturer has it in his power to control the proportions of the materials he uses, and renders it possible for him to make his product uniform. Careful attention to proportions and mixing, and care in the matter of calcination, will produce a cement that seemingly leaves little to be desired. But so long as these details are entrusted to the hands of ordinary laborers—and there seems to be no other way—so long as the natural cements sustain their present reputations, and through their very cheapness keeping down the price of Portland, none but the cheapest class of labor can be employed in the manufacture of artificial cements, and no matter how vigilant the superintendent may be, there will be failures, and sometimes disastrous ones.

Henry Reid, in his admirable work on Portland cement, says: "Chalk and clay, being capable of easy solubility, are charged in their progress through the wash mill with three or four times their weight of water, and theoretically this process appears perfect, but practically, as we shall endeavor to show, there is considerable inconvenience, if not danger, even under the most careful supervision. The difference in the specific gravity of the chalk and clay involves an irregular deposition of the washed mixture, not only in its final settlement in the 'back', but on its way along the shoots. In the most limited works this objection exists, and in the largest in a more aggravated degree, for the farther from the wash mill the liquid material has to be propelled the greater must be the amount of its irregular and eccentric precipitation.". Again he says: "The Portland cement maker has to reduce his raw materials to such a degree of fineness as will permit of their accurate combination, and this can be effected in two ways—the one chemical and the other mechanical. The former, the more expensive of the two, by converting the carbonate of lime into lime, and the silica into soluble silicates, and thus ensure an accurate result, but not one that a Portland cement maker can indulge in, and which we need not further discuss because of its costliness."

In speaking of the dry method, which is simply the mechanical reduction of the raw materials by means of suitable machinery, Mr. Reid says:

"When this is performed in a slovenly, careless or ignorant manner, much danger and expense arise. Doubtless this plan admits of no loose or 'rule of thumb' treatment. Chemically, the lines laid down must be implicitly adhered to, and mechanically, the reduction of the ingredients should be as nearly perfect as possible. There is a danger attending this method, which is sometimes a puzzle to the ignorant, and that is, the want of proper care in applying the necessary moisture to render the mass plastic enough for moulding into bricks (preparatory to calcination). If the water is carelessly thrown on, as is the case in tempering clay for brick making, there is a liability to separate the atoms of carbonate of lime from those of the silicate of alumina, and thus destroy the necessary accuracy of combination so essential to an effective kiln result."

Now here are the two methods employed in the manufacture of Portland cements, the wet method and the dry, and we have shown that both are attended with a danger that must ever be constant, so long as the matter of communition is entrusted to human hands.

While nature did not always deposit her natural cement rock formations in true combining proportions, no handicraft has ever yet excelled or even approached her in the art of mechanical combinations of clay and carbonate of lime, for with natural cements, however much the proportions of ingredients may vary as between the upper and lower layers, there is usually a large percentage of the bed that is so well proportioned as to yield a good cement when all are mixed together. And even the layers that are not properly proportioned, owing to their finely commingled condition, are not as dangerous an element in the mass as is that of an equal amount of an imperfect mixture in an artificial cement. There was imported into this country during the past year about 600,000 barrels of Portland cement, and it is safe to assume that there were not more than 15 analysis made from this enormous amount. That is one analysis for every 40,000 barrels, and, so far as I have been able to learn, no two of these are found to agree.

Furthermore, it is possible to adulterate Portland cements, and, if we are to believe the printed reports of the transactions of the association of Ger-

*Extracts from a Paper read before the Society of Arts of the Massachusetts Institute of Technology, Boston, Mass., by Mr. W. Cummings, of Buffalo, N. Y.

man Portland cement makers, adulteration with slag and other similar materials is carried on by some of the manufacturers to an alarming extent. No one ever heard of a maker of natural cement in this country adulterating his product. It would not pay, for there is no material, useful for that purpose, so cheap to him as the natural cement rock. Honesty, therefore, in this respect, is reasonably well assured.

An over-clayed natural cement will behave better under test than an over-clayed artificial cement. The cause of this is to be found in the much finer condition of the former. Neither of them will act well in frosty weather. An engineer uses what he may consider a first-class natural cement late in the fall, and finds it to scale and disintegrate. He uses Portland in the same way, and it remains firm, and he is more than ever convinced of the superiority of the Portland: But he has unwittingly drawn an unfair comparison. The natural cement that he had selected, however well it may have acted earlier in the season, was over-clayed, and therefore required more water than a well-balanced cement, and consequently it was more liable to expansion and disintegration by frost. It is an error to suppose that the natural cements of this country are all about alike, and that the testing machine will very quickly tell us of whatever differences may exist. A well-balanced cement will withstand the action of frost many years, while an over-clayed one will not, whether natural or artificial, and of this the testing machine gives no indication. If we take two cements, the one being natural and the other artificial, and so nearly alike in composition that a chemist could not distinguish any difference, both being made up of correct combining proportions, the artificial will test higher than the natural product; but can it be truthfully maintained that it is the better of the two?

If we are governed by the prevailing public opinion, we must admit it, for the testing machine says it is so. Had the chemistry of cement and the laws governing combining proportions been made more of a study in the past, we should not now see the whole question submitted to this crucial test, called tensile strain.

Commencing with the year 1825, when Portland cement was first produced, until 1858-60, the natural cements were sold at a price fifty per cent. higher than the artificial cements would bring in the markets of England. Then the tensile strain testing machine was brought into use, and, to the surprise of all concerned, it was found that the artificial products tested higher than the natural brands. This was a revelation that brought joy to the hearts of the heretofore languishing manufacturers, and produced a correspondingly depressing influence over the fortunes of the manufacturers of natural cements. If the Portlands were superior to the natural cements, it is a little strange that such engineers as Grant, Coulson, Mann and others had not discovered it in all those years prior to 1860. But the tensile strain fever had set in, and men argued then, as they do now, that if one cement sustains a higher tensile strain than another, it must be better because it is stronger. And this argument seems unanswerable, and, coupled with the fact that it is a quick and ready means by which the engineer may draw conclusions, has been the cause of its adoption to such an extent that to-day the engineer is considered behind the times who does not have excess to a testing machine.

Looking at this point from the standpoint of one who has had over 30 years of practical experience in the manufacture of cement; witnessing the entire rise and growth of this modern giant, the testing machine; always ready to adopt any and everything looking to an improvement in the the quality of hydraulic cement; studying the action of all the leading brands in the market under varying circumstances, and devoting much time to the deeply interesting study of endeavoring to discover the connecting link that ought to exist between high tensile test and first quality, and oftentimes seeing a cement that was notoriously over-clayed test 600 pounds to the square inch, while another cement nearly perfect in its composition testing barely 60 pounds, and the resident engineer deciding unhesitatingly in favor of the higher testing brand, without a thought bestowed on the question of analysis and combining proportions, and all that goes to render a cement capable of withstanding the changes incident to this trying climate with its extremes of heat and cold, we have sometimes been forcibly reminded of the old adage that "a little knowledge is a dangerous thing."

During the past summer a professor of high repute in one of our leading colleges condemned outright one of the best natural cements I ever knew, a cement that had been thoroughly tried in the construction of masonry in bridge piers, where the current was so powerful and the flow of ice in the spring so terrible that the late Col. Eads declared that no bridge piers could be built to withstand the shock. I mention this to illustrate the workings of the testing machine. If it can deceive a professor in one of our foremost colleges who can it not deceive?

Imagine the fantastic tricks it is capable of playing among the ranks of the city engineers throughout the land. First one brand forging ahead, then another. At last one is reached that shows so far ahead that it soon becomes a hot favorite, and he feels like tying to it. One more trial and it drops away in the rear, and the engineer scratches his head.

(To be Continued.)

A correspondent, writing to *Stone*, says: "It has been quite recently demonstrated that slate, ground up and bolted, can be made into a plastic mass, involving great pressure, and the product then subjected to great heat, changed into an enduring and solid stone. The paste can be formed into anything that can be formed into moulds or by the hands, and everything that is now made from the actual stone can be formed in this way."

GRANOLITHOS—A NEW BUILDING MATERIAL.

By G. F. Stalker.

It is always an advantage to architects to have brought to their notice the qualities and properties of any material, artificial or otherwise, that is intended to be used for building purposes. And as it is on their recommendation that any new material will be brought into general use, or meet with an early death, the inventors of such materials are naturally ready to afford architects every opportunity and facility in their power to satisfy themselves as to their merits. It is not sufficient that a chemical analysis and recommendation should be attached to a new cement or stone. That is good so far as it goes. So also is a proper scientific test of its strength. But to find favor in the right quarter, and to obtain permanence in its use, the new material must be capable of being architecturally treated. For lack of this, many building patents of recent years have made a short successful run, and have ultimately landed the patentees in financial difficulties. The same may be said of such materials as have been made to depend upon cheapness for their success, for some cheap things are very dear, and nothing that can be done with them will ever make them look anything but awfully cheap. At the same time, after being satisfied that a building material is all that has been claimed for it, the next question an architect wants to be satisfied upon is that of its cost.

Granolithos is the name that has been given to a new building material, and, as the name suggests, it is a granite stone. It is composed chiefly of pounded granite and Portland cement, and is, in fact, a similar composition to the granolithic pavement now so well known and so largely used. This should be a strong recommendation of its durability and toughness. And this, together with the fact that before it sets it is very susceptible to impression, induced the Canadian Granite Company to make experiments with a view to the production of a material possessing all the properties of first-class building stone. The nature of the experiments has been such as almost to make success assured. Steps and flight of stairs, with and without nosings, curbs, sills, and other portions of plain masonry were first attempted, and brought to a successful issue. Then diapers, rosettes and other methods of wall decoration so frequently employed in ornamental brickwork and terra cotta. From these to brackets, trusses and keystones successful progress was made, until now there is no kind of architectural detail, either plain or ornamental, which cannot be produced in granolithos, as well as can be done in stone or terra cotta.

The results, taken in connection with the strength and durability of the material, are eminently satisfactory. But granilithos possesses other and very important advantages in regard to its manufacture. It is quickly made, occupying less time in the production of plain or moulded work than stone treated in a similar manner. And, of course, when ornamental work is concerned, the saving of time in favor of granilithos is much greater. Again, it has been found, in the case of nearly every other artificial stone, only possible or safe to produce it in blocks of limited dimensions; whereas granolithos can be made in blocks of the largest dimensions necessary for building purposes. At the same time it can be made in blocks of the size of an ordinary brick; and, in this respect, it will be found a most serviceable material on account of its great hardness, for rounded or square corners, for archways, angles of bay windows and projections where damage is likely to occur. And, as in the process of manufacture, it is not subjected to the influence of heat or any other force having a tendency to warp or distort it, its lines are true and regular, and it suffers no shrinkage in the mass. In color it has been produced, so far, in grey, about the shade of ordinary blue-stone, and buff and red, very closely resembling those colors in terra-cotta.

But, with regard to the important question of cost, it is hardly possible to speak yet with any degree of definiteness. For with granolithos, as with every other material, the price will very much depend upon the amount of detail and ornament shown on the design to be produced in it.

THIS CANNOT BE REPEATED TOO OFTEN.

Stone should never be used immediately after quarrying. It should be exposed to the weather for a month anyhow before it is used. It thus becomes seasoned and will wear much better. When left to season the under side of the rock as it lay in the quarry should be exposed to the sun. When you buy stone for paving or similar purposes insist on its being turned over, that is reversed from the way it was in the quarry before it is laid. The reason for this is that the top surface is much softer, it being of later formation, stone forming from the bottom. *Stone.*

A discovery of sandstone has been made on an island in Johnson Strait, up the coast from Vancouver. The purchaser has, it is reported, bonded it to a Victoria firm for $60,000.

To give a cold chisel a good temper is a question that is somewhat perplexing. We submit the following rule, says the *Chicago Journal of Commerce*, which, if followed in detail, will be found to be the most practical in its results: Heat the chisel to a low heat, so as not to raise the scale, and dip into a brine of salt and water, in quantities of one and ten quarts respectively. Leave heat enough in the tool to allow it being run down to a required hardness, which is designated by the pigeon-blue color. The chisel should be made stout enough to resist a pressure which in using would tend to spring it when put to a test.

VOL. V.—No. V. TORONTO AND MONTREAL, CANADA, MAY, 1892. PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),

PUBLISHED ON THE THIRD SATURDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

14 King Street West, - TORONTO, CANADA.

64 TEMPLE BUILDING, MONTREAL.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1892.

PRESIDENT	S. G. CURRY, Toronto.
1ST VICE-PRESIDENT	KING ARNOLDI, Ottawa.
2ND VICE-PRESIDENT	F. J. RASTRICK, Hamilton.
TREASURER	D. B. DICK, Toronto.

COUNCIL:

WM. G. STORM	Toronto.
DAVID EWART	Ottawa.
S. H. TOWNSEND	Toronto.
JOHN E. BELCHER	Peterborough.
EDMUND BURKE	Toronto.

REGISTRAR AND LIBRARIAN:

W. A. LANGTON — Merchants' Bank Building, Toronto.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1892.

PRESIDENT	F. X. BERLINQUET, Quebec.
1ST VICE-PRESIDENT	VICTOR ROY, Montreal.
2ND VICE-PRESIDENT	J. NELSON, A.R.C.A.
SECRETARY	C. CLIFT, Montreal.
TREASURER	W. E. DORAN, Montreal.

COUNCIL:

A. T. TAYLOR, F.R.I.B.A., R.C.A.	Montreal.
A. C. HUTCHISON, R.C.A.	Montreal.
M. PERRAULT	Montreal.
A. F. DUNLOP, R.C.A.	Montreal.
ALPH. RAZA	Montreal.
J. F. PEACHY	Quebec.

THE painters' strike at Winnipeg, referred to in our last issue, is ended. The strikers have returned to work at the old rate of wages.

THE United States Customs regulations require that to each invoice of granite exported to the States, there must be attached a diagram of each piece so exported and a sworn statement of the value. Enquiries are being made at Ottawa with the view to ascertain what method is employed by Canadian Customs officials to ascertain the value of manufactured granite exported by Great Britain and the United States to Canada.

THE brick manufacturers in Toronto and vicinity have organized an association, and have decided to reduce the scale of wages paid to employés. This action has been promptly followed by the organization of a brickmakers' union, and a determination on the part of the employés to submit to no reduction. The surplus stocks on hand are so large, and the building outlook so unpromising, that some of the manufacturers decided a month or two ago not to operate their yards this season. Under these circumstances, the probabilities are decidedly adverse to any satisfactory results being obtained from a strike of employés at this time.

AN effort will be made at the next session of the Ontario Legislature to have the Mechanics' Lien Act amended in several important particulars. At a recent meeting of representatives of the Toronto Builders' Exchange, Trades and Labor Council, and material supply men of Toronto, this subject underwent discussion. A committee was appointed to draft required amendments to this Act and submit the same for consideration at a future meeting. The discussion brought out the fact that the lien law of Ontario affords less protection to mechanics and persons supplying materials, than laws existing for the same object in many of the States of the Union.

THE Toronto Architectural Sketch Club might profitably follow the custom of English Architectural Societies in visiting in a body as frequently as possible during each summer buildings in course of erection, previously arranging with the architects of the building to be present to explain the points of interest connected with the construction. It is safe to say that one such visit may be the means of affording students more practical instruction than could be obtained from half a dozen lectures. A visit of this character was made to the Hospital for Sick Children on College street, and proved to be of great interest and value. It is to be hoped that a series of similar visits will be arranged for the present summer.

REFERENCE has often been made to the unfairness and sometimes the absurdness of the conditions of architectural competitions. The evil has possibly reached its limit so far as its effects upon architects is concerned. It seems, however, to be now trying to find its way into the engineering profession. The following advertisement recently appeared in the daily papers: "The town of ——— contemplates the construction of waterworks this year, and invites tenders, to be opened 30th inst. Those tendering to furnish their own plans and specifications at their own expense. The lowest or any tender not necessarily accepted. For particulars communicate with———." The above is so palpably a case of "heads I win, tails you lose," that we may presume no engineer will be so foolish as to enter the game.

THE question as to who shall fill the position of City Clerk of Montreal, has not at the time of going to press been absolutely decided, but there is very little doubt that Mr. L. O. David will be Mr. Glackmeyer's successor. He was nominated by the Finance Committee, and in all probability the matter will be decided at the next meeting of the Council. Mr. L. O. David is by no means an unknown man. He has been a prominent figure before the Montreal public for many years, having occupied platform after platform in the interests of the French-Canadian element of the population of the Dominion. He has not heretofore occupied any civic position, but his recommendation by the Finance Committee augrs well for his success in a post of such importance as that of City Clerk of Montreal.

In response to a number of requests, we have decided to publish in the CANADIAN ARCHITECT AND BUILDER for June, the examination papers in connection with the first O. A. A. students' examinations. In this number we present reproductions of a couple of the drawings submitted in these examinations, which will serve to indicate to students taking part in future examinations the character their drawings should assume.

THE Toronto Builders' Exchange is desirous of making some arrangement with the architects which will serve to avoid the delays at present experienced by contractor in obtaining certificates. A contractor who may be doing work for several architects, sometimes finds it impossible to get around to their offices and secure his certificates on certificate day, on account of being obliged to wait his turn in each office. It is suggested that this inconvenience could be avoided by the contractors notifying the architect of his desire to obtain a certificate for a stated amount previous to certificate day, when the certificate could be filled out ready to be handed to him when he might call.

THE Toronto Builders' Exchange, an account of the formation and objects of which was published in our April number, is making satisfactory progress. The membership has increased to such a degree that it has been found necessary to remove to more commodious quarters. These have been secured in the new premises now being fitted up at the corner of Victoria and King streets. The Exchange will take possession of its new home on or about the first of June, and will then have, in addition to a large exchange room, necessary committee rooms and secretary's offices. Mr. John Phillips has been appointed Secretary of the Exchange. It is believed the appointment will prove to be satisfactory. It has been decided to abolish the two classes of membership heretofore existing, and hereafter to allow all members to occupy the same footing. From the fact that during the past month further applications for information have been received from other cities desirous of forming exchanges, it would seem probable that the organization of the building interests throughout the country will be an event of the near future.

RECENT advices from Vancouver, B. C., point to indications of a busy season for the building trades. The unsettled conditions existing between contractors and mechanics, however, are said to be proving a check upon activity. Some of the contractors are reported to be desirous of increasing the working day from nine to ten hours, while others, rather than provoke trouble with the unions, are willing to pay union wages for a nine hours day. The employers very justly complain of the practice of the unions in demanding increases in the rate of wages without giving due notice which would enable them to embody in their estimates the increased cost of labor. These demands for higher wages are most frequently made after contractors have undertaken a large amount of work, the estimates for which have been based upon the prevailing labor prices. The contractors feel, so long as this unfair treatment is accorded to them by the unions, that they are justified in endeavoring to secure workmen from Eastern Canada and elsewhere, even though by so doing the local labor market should become overstocked. An effort should be made to come to an understanding, as is done in Toronto and other eastern cities, under which the rate of wages in the several trades would be fixed for a period of three or five years. Thus the conditions affecting employés, employers and investors would be settled for a definite period.

THE result of the examinations of the Ontario Society of Architects is in every way very satisfactory. They were held too late for us to give the results in our last issue, the reports of the examiners not being in. Since then the Board of Examiners has held its final meeting, made its reports to the Council, and the results have been made public to a certain extent, in the daily press. For our part we are glad to place on record in our columns the names of those who successfully passed the final examination, which we do in alphabetical order: Baxter, D. G.; Bayley, G. M.; Bond, C. H. A.; Brown, J. F.; Gregg, A. H.; Hynes, J. P.; Langley, C. E.; Matthews, H. E.; McCallum, R. J; Munro, W. L.; Smith, Eden, White, M. A.; Woolnough, J. J. The candidates, whether successful or not, have not been allowed, we understand, to know their marks. The examinations have been throughout conducted on the lines of the University examinations, where the marks are known only to the Board of Examiners. On the whole, the passing of thirteen out of nineteen is a very good proportion, and while we wish our new architects every success in the future, we would say to those who failed that there is no reason for discouragement on their part. In many cases to be plucked once is an advantage, and those who were plucked will no doubt set to work earnestly and prepare for a second attack, having found out their weak points. In the second intermediate, nine students passed out of twelve, and in the first intermediate, two out of four. There is to be a supplementary examination some time in September for the benefit of a few candidates in the first and second intermediate classes, whose work at the recent examinations, though not up to the standard, was fairly good, and these will be allowed another chance, that they may be able to take up another stage of examination in the following spring. This advantageous practice of a supplementary examination has a precedent in the procedure of most professional institutions.

TORONTO ARCHITECTURAL SKETCH CLUB.

THE second annual dinner of the Club, held at Webb's, on the evening of April 19th, was the occasion of much enjoyment. In addition to members of the Club, there were present the President and, Registrar and Messrs. Burke, Wickson, Gregg, Darling, Gordon, Bousfield, Simpson, Jarvis and Sproatt, of the Ontario Association of Architects. The School of Practical Science was represented by Mr. Wright, lecturer on architecture, and the contracting interests by a number of persons prominently identified with the various trades.

Mr. J. A. Pearson, President of the Club, presided.

The menu card was an unique affair, and occasioned much amusement. It read as follows:

THE TORONTO ARCHITECTURAL SKETCH CLUB

Specification of work to be done and material to be supplied and consumed in renewing the dilapidated condition of the students caused by the drainage system of the late examinations.

CONTRACTOR
HARRY WEBB

ALL MEMBERS TO COME IN
SPRUCE TIES, COLLARS, BRACES, AND CAST IRON SHOES.

SOUP
OYSTER SOUP, to be carefully lapped
FISH
BOILED LAKE TROUT with herring bone bridging
ANCHOVY SAUCE
POMMES PARISEINNE
BREAD AND BUTTER ridge ROLLS
ENTREES
CHICKEN PATTIES composed of stopcocks, bibcocks, and weathercocks
JOINTS
To be bolted
All carving to be done in an artistic manner
FILLED AND B OILED TURKEY
Well rubbed down under each coat
ROAST BEEF quarter cut, HORSERADISH SAUCE
BROWN POTATOES (Cabot's stain).
YORKSHIRE PUDDING,
All inside work to be well finished up after each course
VEGETABLES
To be filled in and well rammed down in layers not more than 12 inches deep
MASHED POTATOES and STEWED TOMATOES.
ENTREMETS
PLUM PUDDING mixed in proper proportions and stored up at least six months before using.
BRANDY SAUCE.
CHARLOTTE RUSSE with jamb linings APPLE PIE
LEMON MERINGUE PIE CELERY CHEESE
SWEETS
NEAPOLITAN ICE CREAM classic frieze
HARD BURNED CAKES assorted sizes and uniform color
RAISINS and FIGS up to DATE um line
FRUITS
APPLES ORANGES BANANAS
Nuts and Washers as follows
LEMONADE and COFFEE

The whole of the work on completion to be subjected to a smoke test.

The specification was declared to be a most complete and satisfactory one, all cheerfully complying with its conditions. It was observed that perhaps its most unorthodox feature was the provision made for extras. The carrying out of this specification was followed by an interesting programme of speeches and music.

Responding to the toast of "The O. A. A.," the President, Mr. S. G. Curry, referred to the recent student's examinations. Though not resulting as satisfactorily as might have been desired, yet considering that both students and examiners were without previous experience, they should be regarded as having been on the whole fairly satisfactory, and the knowledge gained would afford a basis for improvement in the future. One beneficial result of such examinations was that they served to direct the study of students in the proper direction. He felt assured that a feeling of timidity prevented many students at the late examinations from doing their best. Many absurd answers would have been avoided if the students had been careful to clearly understand the meaning of the questions. As an example of some of the absurd answers given, a student on being asked for a common test for finding impurity in air replied: "Climb upon the roof and put peppermint down the soil pipe." (Laughter). Another student who was asked what would be a

safe load to impose on ordinary clay soil, said: "A frame one or two storey house, or load up to 837 tons." Such answers he believed to be due, as already stated, to lack of proper consideration of the questions. These features of the examinations would doubtless in time disappear. At first it was thought the examinations might be concluded within two days, but it was found necessary to double the period. Even four days was much too short a time. It was not right that students should be compelled to write on an examination for three or four consecutive days. There should be time allowed for rest and study. Two weeks would not be too long a period. The examinations had revealed the fact that students who were supposed to be well up in certain subjects, in reality knew very little about them The O. A. A. should feel grateful to the students who had come forward to assist it in carrying out its objects. The speaker pointed to the fact that an Act was in a fair way to be passed by the New York Legislature under which no man would be able to call himself an architect without having obtained a license to practice in the State. At the next session of the Legislature the O. A. A. should endeavor to have the word "Registered" struck out of the Architects' Act, and by so doing secure a guarantee to the public that persons practicing architecture were competent to do so. The speaker concluded by expressing the hope that the members of the Architectural Sketch Club might be better able than the architects of the present day to do meritorious work.

In response to the toast "Canadian Architecture," Mr. Langton spoke as follows:

People who live in the older countries have inherited the results of the labor of many generations. They live as it were in a completed edifice and enjoy all its comfort and beauty, and, though in some respects life is therefore so much the less worth living, it cannot be denied that there is great pleasure and privilege in being posterity.

We, on the contrary, are ancestors. We are the early Canadians hard at work upon the foundations. We are not cribbed and cabined and confined like our kin beyond the sea, but, on the other hand the glories of our buildings are all in the future. Canadian architecture is rather a subject for speculation than criticism; we may say that Canadian architecture as an established fact as yet does not exist.

There has been much said during the last half century in England about the formation of a modern style. More recently in the United States there has been talk about an American style It was hoped that the late H. H. Richardson had created a style that would become national. It may be true what was said by an English reviewer, that since the architect of the Palace of Diocletian generated Romanesque architecture by taking the column of the Roman order and inserting it under the arch, no one man has done so much to develop a style of architecture as Mr. Richardson. Yet I think it has proved to be a mistake to found on his work the hope of an American style. The school of imitators are one by one turning their attention in another direction. The mark that Mr. Richardson has left upon American architecture is something much wider and deeper than the mere appropriation of the peculiar characteristics of one particular period of architecture. He taught us how to make use of the examples left us from former times by catching from them the spirit of the workman and doing our own work in the same spirit. He did no copying. What he took from an old example was not only adapted but usually improved. In the case of the most salient example of his reproduction of a model—that of the tower of Trinity church—I think we may fairly say that we should have heard very little of Salamanca Cathedral if the tower of Trinity Church had not been built to put honor upon the tower of Salamanca as the original.

I think then we may agree that the Richardsonian Romanesque revival had as much vitality in it as it is possible for a style revival ever to have. Not only was the style adopted made to live in our century but there seemed to be something in the theoretical view taken by approving critics that, inasmuch as the style adopted was an undeveloped style, there was the more hope that the natural law of development should have course with it now that it was revived.

However, the course of work in the United States seems to be moving away from it, retaining only the high standard of taste and the right feeling in design which were introduced into the country along with it, and which I think we may hope are part of the inheritance of American architects and of ourselves henceforth. The right spirit is abroad, and though the architectural world seems to one living in it to be a wild sea of conflicting determinations and shifting views, I think one who has even a slight acquaintance with history will recognize the condition from which have emerged all those results which have formed steps in the world's advance, from which succeeding generations take their start, and to which they always return for their basis. I think we may almost consider that the word style—though in an old country like England, where tradition has force, and where they are empowered by the excellence of the past, still retains its conventional usage as applied to architecture—may with us on this continent begin to have the deeper and better meaning of character, which includes the other and goes beyond it.

To say that a man or a woman has style, is to give to them the highest expression of admiration for their personal charm. Style is beyond beauty, though it often includes it—always includes it in the highest sense of the term. It is the harmonious compound of qualities which makes the man or woman who possess it strike the eye at once, and impress us as distinct. This is what we want in architecture. Not fashion in architectural clothing, but that the building have always distinction of character in accordance with its own programme of requirement, and the conditions of its circumstances. It must be a growth proceeding from the continual effort to satisfy the conditions of our mode of life, our means, our climate, and our material. I doubt if anything can permanently prevent the growth of a true style of architecture, but it may be delayed by temporary fashion quite enough to prevent any of us having the pleasure of seeing it in our life-time. So I want to enlist your sympathy on the right side. You will be soon starting out for yourselves—some of you this year—and your services are wanted in this matter. It is the work of the many, and with a common idea we can progress fast, helping one another by example, as iron sharpeneth iron. The English House of Commons as a body is said to be always wiser than the wisest man in it, and we have no need to wait for the advent of a genius to create Canadian architecture, if we only have in common the idea of making our architecture true. It ought not to be necessary to say much upon this subject so long after the acceptance by the architectural world that in art only truth is life. But we have only to look about us to see that its application still lags.

We have still amphitheatrical churches with a couple of storeys of society rooms and class rooms, all contained within an exterior which represents as faithfully as it can the mediæval church with its single spacious hall. We are are about to have a drill shed here which, inasmuch as it is Government work and the result of tradition rather than individual intention, we need not feel shy of criticizing. It is, of course, to be a castellated structure. In former days arms were kept in a castle. Must, therefore, the building that stores our arms nowadays represent a castle, however feebly? Are we to suppose that when Toronto is surrounded by the beleaguering host, our brave defenders will retire upon the impregnable drill shed and man the battlemented turrets and cornice? We might as well hold that because our grandfathers travelled by means of horses, we should, therefore, build our railway stations to represent as far as possible a stable. I do not want to turn this into a lecture upon truth in architecture, only to take the stand that this only is the course along which our architecture can develop.

There was a little dialogue in this morning's *Mail* which seemed to me to offer a good illustration of the point.

It is as follows:

Artist—"Those evergreens on the north side of your house have a delightful effect."

Farmer—"I should say they had. Them trees keep off the wind and save about $8 worth o' firewood every winter."

That is the whole thing in the nutshell. The farmer plants a row of trees where they are wanted. The trees have a delightful effect. And the more you perceive the usefulness of the trees, the deeper the effect of poetry which they produce. Art and matter of fact are inseparable.

If architecture is to satisfy, the plan must be convenient, and must be expressed in the composition. The construction must be suitable to the kind of building, to the material, and to the climate. This a brief recipe which, however, means a great deal. And I appeal to you if it is not more manly and more worth the devotion of one's energies than always trying to get away from your own problem in imitation of something entirely different.

It takes thought, of course, but you will have at first, when you begin practice a great deal of what has been called "God-given leisure," in which you can invent at your will. You will find also that you know nothing. It will surprise you to find this. It did me. You will have to learn much then, and will have to teach yourselves: and you may as well learn the right way while you are about it. The problems of architecture are limited after all. You must ultimately be at home with them in one way or another. If you will get into the way of handling them rightly you will be better architects, you will be better men, and you will be happier men. You will not find work wearisome as you grow older, but will find in it an interest that mere money making cannot give. And Canada will have buildings that will give pleasure to those who see them, which foreigners will recognize as Canadian, intimately associated with the life of the country—the Canadian style of buildings.

Mr. W. H. Elliott, responding on behalf of the contractors, said the interests of no two classes could be more identical than those of the architect and contractor. In fact, so close was their relationship, that like cats thrown across a rope, they sometimes got to fighting—about what, the architects only know. (Laughter). One lack in relationship would be supplied if architects would refuse to allow contractors to work for less than a fair price. If this rule were adopted, a better class of buildings would be the result. Architects sometimes congratulated themselves upon having secured a low price for their work, but he desired to tell them, if unaware of the fact, that it was impossible to beat the contractor. (Laughter).

Mr A. H. Gregg claimed that the contraction caused by the recent exams, followed by the sudden expansion on the present occasion, left him in no fit condition to respond to the toast to "The Coming Architects." In no way was the world's progress better illustrated than by the facilities for education which were being placed before the rising generation. There was a general

attempt to elevate the standard of all the professions and callings. This extended even to the ranks of the anarchists, who recently placed a charge of dynamite under the School of Architecture at Madrid, but whose plans, like those of many other reformers, were frustrated and their enthusiasm dampened by a callous caretaker. (Laughter). The students were deeply grateful to those members of the O. A. A. who had so disinterestedly sought to promote their welfare. The speaker pointed to the need of a better appreciation of the profession of architecture on the part of the public, and even of persons otherwise refined, and mentioned the case of a lady who was desirous that her son should enter one of the professions, and who brought him to an architect's office, with the remark that as he was somewhat deficient in education she had decided that he should become an architect. The speaker remarked that if the public glance could have rested on the bundle of papers required to be dealt with by the students at the recent examinations, and which, notwithstanding, were but the first fragment of the knowledge to be acquired, they might conclude that some degree of erudition was necessary to the architect.

Some excellent songs were sung between the toasts by Messrs. J. Francis Brown, E. B. Jarvis, R. Wilson, J. J. Woolnough, Geo. Self and Mr. Thomes. Mr. Woolnough also gave a piano solo, and Mr. Jas. Newton some well executed selections on the violin. A couple of recitations were given in creditable style by the President.

The assembly dispersed soon after midnight, having spent a thoroughly enjoyable and profitable evening.

A CASE OF ILLICIT COMMISSION.

The Council of the Ontario Association of Architects desire the publication of the following letter which has come into their possession :

To A. B. C., Esq.,
Architect.

DEAR SIR, I have been accustomed while working under architects in this city, as well as other places, to allow a commission to those who use their influence in my behalf, while letting contracts on alterations, repairs, etc., that they may have in hand. I intended to speak to you on this matter while in your office this afternoon, but failed to get you alone. I will be pleased to arrange matters between you and myself in this way, as I consider an architect and contractor can work together with profit to each other. The time has come when prices are so low that contractors require to scheme a little to come out square. My usual allowance has been five per cent. on all work and two and a half on all material. If these figures are worthy of any notice let us talk together. Yours truly,

Contractor.

It is this sort of thing the Association was originally designed expressly to prevent. The members of the Association are required to sign a declaration binding them to set their faces against illicit commissions in their own practice, and now that the feeling of the profession has been actively enlisted in the matter, contractors who seek to "come out square" by this manner of proceeding will find, sooner or later, that it is not to their own advantage.

OUR ILLUSTRATIONS.

PHOTOGRAVURE PLATE—RESIDENCE OF MR. R. B. ROSS, MONTREAL, QUEBEC—BRUCE PRICE, ARCHITECT, NEW YORK.

RESIDENCE OF MR. E. A. WILLS, GWYNNE STREET, TORONTO—J. FRANCIS BROWN, ARCHITECT, TORONTO.

From the grey sandstone foundation to the first storey window sills is built of red brick, laid in brown mortar, with Portage Entry sandstone trimmings; above this is finished in half-timbered work, starting from a heavy plate bolted to brickwork. The half-timber framing is constructed of 2"x2" studs placed at 12" centres, framed and braced, boarded with wrought boarding, covered with saturated building felt, battened and lathed. The exterior framing is secured to interior framing; the panels are plastered with cement mortar, constituted of cement and coarse sand, colored to harmonize with general color scheme. The interior is well finished in oak and pine. The rooms are spacious, well arranged and heated with hot water. The following contractors did the work: Carpenter and joiner's work, Davidson & Kelly; masonry, T. Self; plumbing, Fred. Armstrong; plastering, F. Beaver; painting and leadglazing, Faircloth Bros. galvanized ironwork, Tucker & Dillon; hot water heating, the E. & C. Gurney Co.

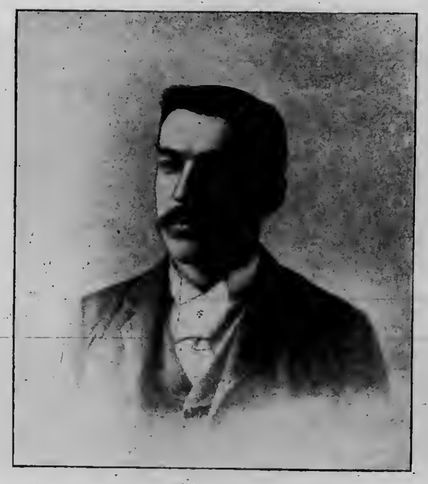
BAPTIST CHAPEL, WALMER ROAD, TORONTO—LANGLEY & BURKE, ARCHITECTS, TORONTO.

O. A. A. EXAMINATION IN DESIGN. SKETCH FOR CHURCH SUBMITTED BY J. FRANCIS BROWN, TORONTO; SKETCH FOR HOUSE SUBMITTED BY W. MUNRO, TORONTO.

We publish elsewhere a list of tests of the Thorold cement, which are claimed by the manufacturers to be the highest tests ever made of any Canadian natural cement.

CANADIAN CITY ENGINEERS.

VI.



MR. F. W. W. DOANE, CITY ENGINEER, HALIFAX, N. S.

Mr. F. W. W. DOANE, City Engineer of Halifax, Nova Scotia, was born at Barrington, Shelbourne Co., N. S., on May 31st, 1863, his father being Capt. Harvey Doane, well known in his native province.

The subject of our sketch began engineering work in 1882. From 1883 to 1891 he was assistant to the provincial government engineer of Nova Scotia. During that time over $1,000,000 was expended on highway bridges. The work of the Department also included railway surveying and construction, water supply, sewerage, laying out, construction and repair of public roads, and reclamation of land from the sea. In 1886, Mr. Doane was sent out on the survey of the Musquodoboit Valley and Stewiacke Railway; in 1889, on the Carleton Branch Railway and Western Shore Railway, and in 1890, on the Heatherton and Guysboro Railway and North Colchester Railway. In June, 1891, he was appointed City Engineer of Halifax, N. S. The duties embrace all kinds of city works, such as engineer and superintendent of water works, charge of public works, street grading, paving, repairs, &c., sewers, maintenance and repairs of city property, and all improvements.

Mr. Doane has recently recommended the construction of new sewers estimated to cost $75,000, and submitted a report to the City Council on a scheme for improvement in the city water supply. A new 27" main is to be laid, new dams and gate houses constructed, and storage capacity increased 275,000,000 gallons. The improvements are estimated to cost $200,000. There have also been inaugurated extensive street and sidewalk improvements, which it is expected will add greatly to the appearance and reputation of the city.

In co-operation with the Board of Health, the Engineer is thoroughly reforming the plumbing system and sanitary arrangements of the whole city (of which there was very urgent need).

Mr. Doane is probably the youngest member of the Canadian Society of Civil Engineers.

He has been a member of the Council of the Institute of Halifax since 1888, and is likewise a member of the Faculty of Pure and Applied Science of Dalhousie College and University, being lecturer on civil engineering and surveying.

ONTARIO ASSOCIATION OF ARCHITECTS.

The following is the official list of the results of the recent examinations :

Admitted to registration as members of the Association: Messrs. D. G. Baxter, G. M. Bayly, C. H. Acton Bond, J. F. Brown, A. H. Gregg, J. P. Hynes, C. E. Langley, H. E. Matthews, R. J. McCallum, W. L. Munro, Eden Smith, M. A. White, and J. J. Woolnough. Conditioned—Messrs E. A. Bird, W. G. Burns, W. W. Pease.

Second intermediate examination: Passed Messrs. F. P. Kelley, Wm. Rae, A. E. Wells. Conditioned: Messrs. Kenneth Gordon, T. R. Johnson, H. G. Macklin, R. B. McCiffen, J. V. Munro, Geo. M. Scott.

The supplemental examination for conditioned candidates will be held in next September.

It is not proposed in future years to admit candidates for the final examinations to a supplemental examination. On this occasion, as many of the students presenting themselves for the final examination have been obliged to wait for the instruction of the examinations, and so have served terms longer than required by the Association, the council has appointed a supplemental in order that the candidates may be hindered as little as possible in proceeding to practice.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

Mr. J. A. Chausse, architect, is removing his office to No. 153 Shaw street.

Mr. A. Dubrueil, architect, has removed from No. 1639 Notre Dame street to No. 1608 on the same street.

THE Province of Quebec Association of Architects in a communication to the City Clerk, urges the importance of the office of sanitary inspector, and the consequent necessity for caution in the selection of a competent person to fill the position.

"L'Association de Secours des Ouvriers," is applying for letters of incorporation, with the object of assisting workmen or workwomen who through misfortune are unable to provide for their own maintenance. Applicants for such assistance must furnish if required a certificate of good behavior. The capital stock of the Association is to be $12,000. A number of prominent Montreal contractors are interested in the movement.

HOW TO ESTIMATE.

By W. H. Hodson.

BELOW are printed specification and bill of quantities for excavator, mason and bricklayer, accompanying working drawings of Baptist Church, Walmer road, Toronto, appearing in this number.

EXCAVATOR, MASON AND BRICKLAYER.

Erect the necessary hoarding in accordance with city by-laws. All vegetable mould to be put to one side for top dressing. Excavate the ground as required for the basement, footings of walls, piers and buttresses, and for drains. Excavation to be 9 in. clear of walls to permit of pointing and inspection. Fill in and ram to walls after inspection; level to grades shown. Any soil not required for levelling to be removed from premises. Execute drainage as shown with approved salt glazed vitrified pipe of Scotch or American manufacture, jointed in Portland cement and laid to proper fall with all necessary bends, traps, junctions, etc., complete. Put McGuire's cleaning out trap with connection for cleaning carried to within one foot of surface of cellar. Lay weeping drains, as shown, in boiler pit connected with main drain behind proper glazed pipe trap. Connect drain with sewer in street, paying all fees. Footings of walls to be of large flat stones not less than 6 in. in thickness and 4 in. on each side wider than the work above, and to extend to at least half the width of wall above. The footings of large piers carrying main columns to be in two courses of stone of approved quality, 8 in. thick and not more than two stones to each course. Footings of main chimneys to be similar, with not more than three stones to each course. The footings of tower to be similar. The bottom stones to be in length the full width of footing (5 ft.) and not less than 3 ft. wide, the next course to be similar, 4' 2" long, and the next 3' 4" long. All to be of even thickness, flat on bed and set on a one inch bed of one-third Portland cement mortar. All the footings of main walls and piers to be set in mortar of similar description. The stone walls above finished ground line on north and rear elevations and corridor to be finished with a narrow course of brown Credit Valley stone neatly pointed with brown mortar. The walls on east and west elevations and part of north, as shown, up to level of ground floor window sills, to be faced with the best Credit Valley brown stone in courses of varying heights, and well bonded into wall behind with at least one bond stone to each superficial yard of walling. Stones to be boldly rock faced with narrow margin drift at angles and laid up in dark brown mortar (Cabot's or Pecora) with deeply sunk joint. The walls above coursed work (on tower, east and north elevations) as tinted brown, to be of brown Credit Valley stone in random ashlar work of most approved description, well bonded into brick backing and laid up in similar mortar with similar joint as above. No stone to be more than 9" in height and a preponderance of long thin stone to be used. The reveals and weatherings to be neatly chiseled, and angles to be finished with narrow margin drift. The walls above the stone work to be carried up in good brick work, composed of the best hard burned bricks laid in the best prepared mortar, well finished up. The outside to be faced with best machine moulded dark red bricks of even color, laid English bond in dark brown mortar, similar to that for stone work, having a deeply sunk joint. The inside of porch and vestible at rear to be faced with similar bricks of lighter color in the dado; quoins, etc., and with picked white bricks in the walls, all laid American bond and to harmonize with work in present school building. The red bricks of the interior to be laid up in mortar colored with Cabot's red mortar stain, and the white bricks with mortar colored with Cabot's yellow mortar stain, all finished with a neat bead tool joint. The internal window sills to be finished with a course of plinth bricks. The capping of dado to be a plinth brick reversed. The walls of porch and vestibule to be hollow and two half bricks thick. Outer face to be well parged. Tie the half brick walls with stout hoop iron every fifth course and about one foot apart; iron to be bent ⊔ thus and dipped in tar. The outer 9" walls of dressing rooms and vestry to be built English bond. The walls of church to be also built with a 2" cavity tied with hoop iron as before mentioned, the inside face of outer wall to be carefully parged. The inside walls of auditorium, front vestibule, north stairway and tower (two stories) to be faced with No. 1 pressed bricks in the very best and most workmanlike manner, laid up in English bond with a narrow joint in putty mortar to harmonize in color with the bricks. The dado, the moulded bricks in jambs and arches of the west end and the belts and friezes at east end to be executed with pale brown bricks equal to sample in the architect's office, the walls above dado to be faced with bricks of a yellowish buff tone equal to sample shown. The capping of dado, the angles, jambs, sills, arch bricks and labels as shown to be executed with moulded bricks of approved design; supply moulded bosses, returns or stops where required. State reduction if all pressed brick work inside (except fireplaces) be omitted and walls (of hollow and similar thickness) left rough for plastering. The jambs, arches and labels of the three entrances in east elevation, windows adjoining and three windows above to be executed with No. 1 pressed and moulded dark brown bricks of approved design laid up in mortar of harmonizing color. The labels over windows in south elevation to be of moulded pressed bricks finishing to moulded stops. There will also be moulded stops to labels of three windows on east elevation. Dentil bricks at eaves of staircase to be moulded and pressed, jambs of staircase windows to be simply rounded.

Brick piers in cellar to be of hardest grey or red bricks, built perfectly solid and having neatly struck joints. The walls of boiler pit to be built with similar bricks in 4" stone footings, joints to be neatly struck. Carry up flues as shown, properly parge the same, and provide and build in cast iron slides to give access for cleaning smoke flues. Provide and build in 15" collar in smoke flue with chimney stack. Form fireplaces as shown, those in church to be faced with No. 1 pressed brick of color to harmonize with dado, and having moulded brick courses as shown. Turn arches on wrot. iron camber bars. Form ash dumps properly parged and furnished with cast iron soot doors in cellar. Build brick trimmer arches and level up with concrete to within 1½ of finished floor line. Build vent flues from below ceiling of gallery as shown, two to be carried up in walls of tower into pinnacles, two in south side to be carried into pinnacles of transept, that in north side to be carried into flue in vestry chimney stack, and that at n. e. staircase to be carried up to eave line. The openings in inside to be filled with 12" x 18" white enamelled valve registers provided and set by mason.

Arches to windows and doors, &c., to be cut and gauged. Turn proper relieving arches over all openings of at least two rings. Thoroughly clean down all walls (the internal ones with acid), removing all stains or defects, cutting out and replacing any discolored or broken brick, and leaving all perfect on completion. Bed in mortar all wood slips, wood bricks, stone or other work required to be set in the masonry or brickwork. The walls of vestry and dressing rooms will have strips built in for securing battens. Bed in mortar all lintels, plates, etc., and carefully point round all window and door frames. Cut all necessary grooves for flashing, and point up as required. Beam fill on all walls to underside of roof and floor boarding. Build areas of hard bricks in stone footings and pave with brick on flat. Build in carpenters' bolts for copings. Provide good and sufficient scaffolding which is to remain for the use of other trades as required. Take every precaution to prevent walls being discolored from splashings from scaffolding. Form foundation for boiler, say 40x12 ft. with flat stone 4" thick and on this lay hardest clinker bricks set on edge in sand and well flushed. Lay the boiler pit with similar bricks set in a 4" bed of sharp sand. The coal and ash pit and space adjoining as tinted grey will be concreted. Excavate to additional depth to allow for boiler. Form foundation with stone chips 6" deep and on this lay concrete floor 5" thick formed with coarse gravel, coarse sand and Portland cement in proper proportions and floated to a smooth and even surface. Provide and set on brick piers under the eight main columns squared and dressed approved stone 32" x 32" x 12" thick. The piers carrying six small gallery columns to be coped with approved stone 8" thick and those carrying beams with stones 4" thick. All to have dressed beds and to be correctly squared. Provide similar stones 8' x 12' x 4" under beams when resting on walls. Cope walls of ash and boiler pit with approved stone 9 in. x 4 in. thick in long lengths, dressed and carefully set in Portland cement. Cope chimneys with Credit Valley or other approved brown stone 9 in. thick, and in not more than two pieces to each stack, cramped and set in Portland cement. Sills of basement windows to be of Credit Valley stone (brown where exposed). Sills of vestry and dressing room windows may be executed in Beren or brown stone of approved quality, seated, weathered, throated and rock-faced. The heads, strings and sills of all other windows to be executed in the best description of Credit Valley brown stone, free from all flaws and defects, tooled or chiselled as may be directed, weathered, seated and throated. Sills at random work may be rock faced. The steps and landing at main entrances to be of same Beren or equally approved stone, carefully set in long lengths in Portland cement and joints thoroughly flushed. The coping of parapet of front gable to be of approved brown Credit Valley stone in long lengths, set in Portland cement and weathered, tooled and throated as directed. The carving of the four bosses at entrances and the finial on coping is reserved. Prepare for carving as required. The eight corbels, side walls under principals, and the two corbels at the east end carrying foot of principals, the four corbels under iron beams at tower and staircase openings, the four corbels under gallery brackets, the cornice at spring of arches at west end, and the heads of two fireplaces to be of light brown stone of approved description, moulded and rubbed. Sills and exposed stonework to be boarded over immediately upon being set.

BILL OF QUANTITIES.

EXCAVATION AND DRAINAGE.	$	c.
Board fence, etc., as per city by-laws		
1100 cubic yards of excavation, basement walls, piers, buttresses and drains; includes filling, ramming, levelling, etc., etc.		
101¾ lineal yards of vitrified pipe drain; includes bends, traps, junctions, etc.		
13 lineal yards of 4 in. weeping drain, complete		
Provide 9 in. continuation drain from sewer to street line at per lineal yard, complete, paying fees for same		
1 McGuire's cleaning out trap with connections		

NOTE.—Excavations are measured "cube," that is, length, breadth and depth, thus: 54 ft. 9 in. x 22 ft. 6 in. x 5 ft. 6 in. = equal to 6775 ft. 4 in. divided by 27, the number of feet in a cubic yard, gives 251 cubic yards, less (1 ft. 8 in). Tile drains are measured lineal, that is, running measure, as indicated in above items.

MASONRY AND CUT STONE.	$	c.
157 toise of masonry complete, including the footing laid in cement		
2080 supl. ft. of coursed Credit Valley brown stone, varying heights pointed in brown mortar, includes margin, draft, etc., chisseled reveals		
20 supl. yards of foundation to boiler 6 in. stone chips and 3 in. thick concrete, smooth surface		
131 lineal ft. of narrow coursed Credity Valley stone, pointed in brown mortar		
72 lineal ft. of Credit Valley brown stone coping in long lengths set in cement		
50 lineal ft. of Credit Valley brown stone coping, parapet of front gable, long lengths, set in cement		
18 Credit Valley cut stone sills, 6 ft. 6 in., weathered, throated and seated		
7 Credit Valley cut stone sills, 5 ft. 0 in., weathered, throated and seated		
5 Credit Valley cut stone sills, 3 ft. 6 in., weathered, throated and seated		
10 Credit Valley cut stone sills, 2 ft. 6 in., weathered, throated and seated		
7 Credit Valley cut stone sills, 2 ft. 0 in., weathered, throated and seated		
8 column stones, 32 in. x 32 in. x 12 in.		
6 coping stones to gallery columns, 8 in. thick, dressed		
6 coping stones to beams, 4 in. thick, dressed		
8 stones for beam rests, 12 in. x 8 in. x 4 in., dressed		
2 coping stones of Credit Valley to chimneys, in two pieces, set in cement and cramped		
26 light brown stone corbels front of principals, spring of arches, etc., etc.		
4 boss stones (for carving) and finial		
2 Berea stone steps and landing, main entrances, in long lengths set in cement		
4 double footing stones in cement mortar under iron pillars		
Boiler foundation, 480 ft. of flat stone 4 in. thick, covered with hardest clinker brick set on edge; well flushed		

NOTE.—Masonry is measured cube and the totals of dimensions added together, divided by 86, the number of cubic feet in a toise. The French measure per toise being 6 ft. x 6 ft: x 2 ft., equivalent to 6 ft. 4½ in. x 6 ft. 4½ in. x 2 ft. 1½ in. English measure, the French foot being ¾ of an inch longer than one foot English. Cut stone facing measured superficial, that is, square, thus: 5 × 5 gives 25 ft.

BRICKWORK.	$	c.
60,000 (A2) best hard burnt brick, with white, red and plinth, to sills, and reverse to dado, a proportion of pressed and pale brown brick equal to sample bricks, etc., smooth jointed		
27,500 machine made bricks, laid in brown mortar, tied with hoop iron at cavity		
6,100 (A1) red and white and pressed brick facing to porch and vestibule		
2,900 hardest grey bricks to piers		
2,300 bricks, moulded for dado capping, angles, jambs, sills, arches, lables, etc., etc.		
1,000 dentil moulded and pressed bricks to staircase window		
170 hardest clinker bricks to boiler pit, on bed of sharp sand		
23 supl. yds. of concrete; to coal and ash pit		
800 hoop iron ties dipped in tar		
50 relieving arches, double rims, throughout building		

	$	c
4 12 in. x 18 in. enameiled valve registers, complete		
2 cast iron slides to smoke flues		
2 15 in. collars to smoke flues		
Arches over two fire places and wrought iron camber bars		
Ash dumps and cast iron soot doors in cellars		
Trimmer arches and concrete to within 1½ in. from floor		
Vent flues from gallery ceiling, two to be carried up into wall of tower and one in vestry; chimney stack up to eave line		
Cleaning down walls, removing stains and defects, bedding timbers, building in strips for battens, pointing to windows and door frames, grooving for flashing, beam filling, bolts for coping, etc., etc., complete		
Scaffolding as required and remaining for other trades		
Deduction if A 1 and 2 is not carried out		
A 1 deduction, pressed brick ommitted and instead left rough for plasterer		
A 2 deduction, pressed brick omitted and instead left rough for plasterer		

NOTE.—Brickwork is measured cube and in Montreal the number of bricks given in estimating is 20 bricks to the cube foot, and is ascertained thus:

6 bricks long say 4" 0"
9 " high " 2' 0"
54 8' 0" = divisor.
3 brick thick

8 | 162 | 20 to the foot.
16

The openings are measured and deducted from the solid work. Concrete when not deep is measured by the superficial yard, thus: 3 ft. x 3 ft. gives one yard. Concrete in heavy work is measured cube, 3 ft. x 3 ft. x 3 ft., or 27 ft. to the cubic yard. Arches, etc., are given in numbers and other items noted as above.

(To be Continued.)

SANITATION & HEATING

VENTILATION.*

SOME extracts from various reports of scientific men on the subject of the ventilation of Halls of Assembly which from many years of study I believe to be the best solution of a very difficult problem:

Two systems of ventilation so far appear to have been adopted, viz., the upward or the downward exhaust.

The fundamental principles of ventilation are:

1st. Heated air is relatively lighter than colder air, and will continue to ascend and the cold air to descend so long as they are free to move.

2nd. More or less than a given quantity of air practically considered cannot occupy an apartment and cannot be introduced unless an equal quantity be withdrawn, or withdrawn unless an equal quantity be introduced.

These two simple and self-evident propositions will explain nearly all the phenomena observable in ventilation. The first method adopted by engineers and architects to give movement to air for the ventilation of mines and buildings was to heat an upflowing column, thus lessening its specific gravity and causing it to rise with corresponding force. That system was employed in the British Houses of Parliament, where in many of its towers a charcoal fire was kept burning and thus a force obtained to propel the air through the building. It has been practically demonstrated, however, that one pound of coal burned in the furnace of a steam boiler to drive a fan blower will generate as much force and consequently is capable of producing as strong a current of air as 38 pounds expended in heating a column of air to act by its diminished gravity. If heated air is introduced into an apartment containing air at a lower temperature through registers at the floor, it rises rapidly to the ceiling, and if there are openings at the ceiling it escapes without (except in a very slight degree) mixing with the air in the apartment. The air that passes off in this manner is absolutely lost and the heat imparted to it wasted. It does not remove the vitiated air contained in the lower part of the apartment, it does not form with it a homogenous mixture and does not communicate to it more than a small portion of its heat.

But if, instead of escape openings at the ceiling they are placed at the floor, the phenomena observed will be widely different. The heated air will as before rise to the ceiling, but instead of escaping, will press the colder air downward to the exit ducts and fill the apartment with pure warm air; the air vitiated by breathing will at once sink below the level of the mouth and in a few seconds will be carried off, no accumulation of foul air being possible.

Various opinions are given as to the amount of fresh air necessary to render the products of transpiration and respiration innocuous. These estimates made by distinguished observers vary from 2 to 50 cubic feet per minute. These estimates and are generally based upon the hypothesis that the fresh air introduced into an apartment mixes uniformly and homogeneously with the vitiated air and dilutes it to an extent to render it innocuous; but if instead of mixing with the air of the apartment, the warm pure air should rise to the ceiling and escape, all conclusions based on the hypothesis of homogeneous mixture would be fallacious. If the air that has once been respired could be immediately removed without being the second time taken into the lungs, it is obvious that so far as respiration is concerned no more need be introduced into an apartment than can be breathed; this amount is easily calculated.

At a temperature of from 65° to 70° Fahrenheit the following average results are given by Dr. Wetherill for the respiration of an adult: Number of respirations per minute, 20; cubic inches of air inhaled at each respiration, 20; cubic inches per minute, 400. The carbonic acid exhaled is stated to be 15 cubic inches per minute, and the surrounding air vitiated is 2½ cubic feet per minute. Four hundred cubic inches is less than one fourth of a cubic foot and this is all that can be taken into the lungs per minute.

The House of Representatives at Washington is provided with 60 cubic feet per man per minute, and yet the vitiated air is not removed. The quantity of air introduced is twenty times as great as the quantity that could be vitiated by respiration provided there was a homogeneous mixture. The facts which are daily observed prove that such a homogeneous mixture does not exist under the present system. If nineteen-twentieths of the heated air which enters the apartment escapes without being utilized, it follows that nearly all the fuel consumed in heating it has been wasted.

In the process of respiration 15 cubic inches of carbonic acid per man per minute are ejected from the lungs. This gas in course of time would diffuse itself throughout the apartment, but it is well known that its density is so great that it can be poured from one vessel into another, or if poured into an inclined trough it will flow downwards, extinguishing successively a row of lights.

The specific gravity of this gas is 1.52 or 52 per cent. heavier than air. Its tendency would therefore be when exhaled to sink below the level of the mouth and occupy the lower portions of an apartment near the floor, but it has been supposed that the elevated temperature at which it is projected from the lungs causes this gas to rise and escape at the roof; the fallacy of such an opinion can, however, be readily proved. Even if the temperature at which carbonic acid escapes from the lungs should be so elevated as to render it momentarily lighter than the surrounding air, it would soon part with the excess of heat and then seek the level due to its superior density—but in fact under the condition of things which actually exists there is only 20° difference in temperature between the air when first expelled from the lungs and that of the apartment. As air increases in volume 1-460 of its bulk for each degree of Fahrenheit, the effect of increasing the temperature 20° would be to reduce the specific gravity less than ten per cent., and the carbonic acid upon leaving the lungs would still be 40 per cent. heavier than the air of the apartment. It would seem impossible for this dense gas to rise to the ceiling and escape at that level without a violation of the laws of pneumatics, unless by powerful mechanical means.

Dr. Wetherill reports that each flame of gas consumes as much oxygen and gives out as much carbonic acid as five human beings.

General Morin reported that a ventilation of 14½ cubic feet per man per minute *principally downward* left no perceptible odor in a lecture room, while the upward ventilation of the Halls of Congress with 60 cubic feet per minute, is notoriously defective.

As regards the direction the products of respiration take after leaving the body, the evidence in support of the tendency to rise is from a report from the Smithsonian Institution; its author seems to have smoked a pipe at the Institute and the smoke ascended—but the objection to this experiment is that tobacco smoke is not one of the ordinary products of respiration. The experiment does not prove that the gray smoke which was seen to rise was carbonic acid. The experimenter does not state in what direction were the ventilating currents in the apartment or how produced, and there was nothing in the experiment to prove that with a gentle downward ventilation the smoke would not have moved downward instead of upward—in fact it proved nothing at all in reference to the direction of the products of respiration.

Lewis L. Leeds quite agrees with General Herman Haupt in conclusions both as to theory and the necessity for putting in practise a system of exhaust for ventilation from the floors of the house, and says very extensive practise and close observation for many years past have fully convinced him that the human breath, which is the great source of contamination tends first towards the floor in a still room of 70°, and that there is a probability in a closely occupied room that there will be quite an excess in the accumulation there. This applies to rooms warmed exclusively by heated air. The contrary opinion—that is the assumption that the breath and the impurities exhaled from the body rise to the ceiling and accumulate there—was advocated strongly in the ventilation of the English House of Parliament, and it is reported that some two or three millions of dollars were spent in endeavoring to heat and ventilate that building comfortably, and as the proceedings in regard thereto were spread over the world to an extent probably one hundred times greater than any previous publication or action in regard to ventilation of any public building, that theory of ventilation became strongly impressed upon the public mind as being the correct one. I consider that idea erroneous, hence all theories of ventilation based upon it are consequently wrong. In the majority of our rooms the heated air entering (which, of course, must assume to be pure air) does not enter warmer than the contained air one half of the time and probably not more than one quarter of the time. Mr. Leeds goes on to advocate an open fire and further states "I believe it would be at all times and under all circumstances very desirable to have a large amount of the air drawn from the floor as nearly as possible under or near each member's seat, and also from under the seats of all the benches in the galleries, but to know how or when and how much to draw from the ceiling would be a much more difficult question to decide. That there should be such openings we know from everyday experience, the necessity for opening doors or lowering external windows to relieve the upper part of a room when it gets too warm. The openings at or near the ceilings require to be closed or opened according to the varying conditions of the room. Heat applied within any building causes movements of the air with more or less force according to the difference of temperature of the external and internal atmosphere. The external wind is a source of considerable power. It is important in the application of power, either to make it conform to and co-operate with the natural forces and merely assist their action, or otherwise make it of sufficient power to entirely overcome all these natural forces—if much care is not exercised in the adjustment of these forces one just counterbalances the other and stagnation is the result. Scientific and medical authorities generally concur in the opinion that in-door air after heating should contain nearly the same proportion of moisture as the average of out-door air of the same temperature, but when air is brought in from out of doors at a temperature of zero and raised by heaters to 68°, it would require the addition of 4.343 grains of water per cubic foot of air to bring it up to the required degree of moisture. For the proper moistening then of fresh, warmed air introduced at the rate of 20 cubic feet a minute for each one of three hundred persons two hours, the air taken at zero and at an average degree of moisture, no less than fifty-nine gallons of water would be required to be added. Exactly how much vapor or what per cent. of moisture is the most healthy has not yet been determined. From much observation we have taken 65 per cent. of saturation as the amount most likely to prove healthy—the mean relative humidity of the air at Philadelphia for the year 1863 was 57.2, and the mean average for twelve years, 68.5.

Dr. Wetherill in his report on ventilation of the Capitol at Washington says: "Hood, ("Warming and Ventilation,") estimates the air required for ventilation by the amount needed to take up the moisture from the skin and lungs. The air required for respiration (*i. e.* oxidation) is very much less than that needed to hold in solution the vapor of the skin and lungs, which evolve 12 grains of water per minute.

If the temperature of a room be at 60° with a dew point of 45°, a cubic foot of air will absorb 2½ grains of vapor, or, in other words, the perspiration from the body will saturate 5¼ cubic feet of air per minute. If, however, we take the dew point lower, say not to exceed 20 or 24°, then 3¼ cubic feet of air per minute will be required to carry off the insensible perspiration, while, for the pulmonary supply one-fourth of a cubic foot will be needed, making a total of 4 cubic feet. In summer, as the dew point is higher, more air will be needed, viz., 5 cubic feet per minute for summer ventilation. In a foot note to the above it is stated that Seguin gives the exhalation of water from the lungs, 7 grains, from the skin, 11 grains, total grains, 18 per minute. If the dew point is maintained uniformly at 52° the following is the calculation of quantity exact for this case: A cubic foot of air at a temperature of 65° with the dew point at 52° will absorb 2½ grains of vapor, and if we take the mean of the two authorities above cited regarding the quantity exhaled by each person, we will have 15 grains per minute, and to absorb this under the above conditions will require 6 cubic feet of air. Add to this the one-fourth cubic foot required for breathing, and we have 6¼ cubic feet as the total amount vitiated per minute. The surface of an average man is about 18 square feet. If, therefore, we imagine such a man walking in the pure open air at the rate of two miles an hour on a perfectly calm day the air will be flowing past him at the rate of 176 feet per minute, and as he is one foot deep from front to back, the average thickness of the envelope of vitiated air which surrounds him may be found as follows:

Let A = The quantity of vitiated air per minute in cubic feet . . 6¼
B = The surface of the person in square feet 18
C = The extent of the person in direction of the current of air in feet 1
D = The velocity of the current in feet per minute 176
x = Thickness of envelope in inches

$$\text{Then } \frac{12\,A\,C}{B\,D} = x$$

and x = 0.018 or 1/55 of an inch.

In supplying air for the upward ventilation of a hall containing an assemblage of people, however, it is absolutely essential that the direction of the current should be vertical, otherwise that which has been vitiated by one person would be given to another to breathe and perspire into. If we now assume a man standing upright of the average height of 5' 6", and the velocity of the current at 5 feet per minute, we will have for the value of the terms in above formula: A = 6¼; B = 18; C = 5²/₃; D = 5; whereupon x = 4.16 inches.

If this envelope of 4" thickness be drawn upward, it is clear that the nose and mouth will be always supplied entirely with vitiated air, no matter how pure it may be one foot away, while if it is drawn downward those organs will always be supplied with perfectly pure air. This consideration alone is quite sufficient to determine in favor of downward direction; there are, however, some other advantages in the downward over the upward direction. The temperature of the human body varies 2° either way from 98°, a sudden variation of 5° or 6° being said to be fatal. If, therefore, the air is supplied at a temperature of 65°, it will be 32° cooler than the body. With a downward current the head will be in this cool air while the feet will be inclosed in an atmosphere nearly if not quite as warm as the blood within them, and to "keep the head cool and the feet warm" is one of the fundamental rules of hygiene as well as of comfort.

A current of air coming up through the floor will always bring along with it the fine dust which the greatest care cannot prevent accumulating there to an extent which renders it unpleasantly sensible in all assemblages supplied with an upward ventilation. With the downward ventilation it is only necessary that the dust shall be thoroughly removed from the inflowing air at the mouth of the inlet duct to maintain the hall perfectly free from dust.

Again, with upward ventilation the entire hall is filled with vitiated air, the vitiation having taken place near the point of admission, while with the downward ventilation the ventilation takes place near the point of exit and the whole upper part is full of pure air. In a hall say, 36 feet from floor to ceiling, and the fresh air is admitted through apertures well distributed in the ceiling—it has thirty feet to move before it comes in contact with the heads of persons on the floor. During this movement all eddying currents induced by the increased velocity with which it is necessary that it shall pass through the apertures have become quiet, and the whole mass descends with an uniformity impossible to obtain in the vicinity of persons ventilated with upward ventilation, and one of the most important considerations to be kept in view in ventilating an apartment is to avoid perceptible draughts. Mr. Goldsworthy Gurney, in his examination before a Committee of House of Lords, said: "We have found the down current always more agreeable; the up current is sometimes used, but it is not so pleasing and not so effectual."

One objection used against the downward system is that it is against nature to force air downward. Although this opinion is entertained by an extremely large number of otherwise well-informed persons, every engineer of ordinary attainments knows perfectly well that it is as easy to force air in one direction as another. Another objection is, that as air is additionally warmed at the same time it is vitiated, that which is vitiated and warmed has a tendency to rise whatever may be the direction of the general mass surrounding it. This is true, but this tendency is so feeble that its opposition to a current of 5 feet per minute would not be perceptible. It has been shown that with a vertical current of 5 feet per minute the mean thickness of the envelope of vitiated air surrounding a man of the average size when standing is 4", this more than two hundred times as thick as when he is walking at the rate of 2 miles an hour in a perfect calm. As, however, the air has to be brought from such a direction that mouth and nose are always supplied with air of absolute purity, to insure the control of its direction by mechanical means, a current of 5 feet per minute has been assumed for the minimum velocity to be given.

When the weather is fine, or in other words, when the outer air from which the supply is derived is in the desired condition as regard temperature and moisture, and no expenditure is required upon its conditions, then a maximum amount may be given, the minimum being employed when its condition as regards temperature and moisture has to be changed to the greatest extent. The only limit to the amount of air it will be advantageous to supply is that fixed by the rule that the currents past the person must not be sufficiently rapid to become sensible.

Some persons are sensible to currents of much less velocity than required to render others conscious of them. Most people can feel a current having a velocity of 150 feet per minute, very few can perceive one of 90 feet per minute. To be quite sure that no one, however delicate, should be conscious of being in a current, the maximum current would be safe at 50 feet per minute. But 10 feet per minute will give a bountiful fresh ventilation. The average thickness of the vitiated envelope will then be two inches, or one hundred times thicker than when walking out doors in a calm. With downward ventilation, however, the nostrils are in pure air equally as when walking, the vitiated air enveloping the lower part of the person only, leaving him unconscious of its presence.

Even when the weather is good and the temperature of the air delightful and the wind blowing with the most desirable force, an open window in the side of a great hall filled with an assemblage of people would furnish air to those furthest from the window filled with emanations of all the persons it has passed on its way.

That the air as vitiated has a tendency to rise has been a favorite theory among scientific men. Mr. Gurney was one of the first to stoutly deny the fact in his testimony before Committees of Parliament; he asserted that the downward propulsion which the breath received by the position and direction of the nostrils did not cease so far as the impurities with which it is laden are concerned, till it deposited them on the ground, also that on a frosty day the vapor from a person's mouth may be seen to describe a parabolic curve to the ground. But any one may see

* Paper by Thos. Fuller, Chief Architect, Dominion Board of Works, read by Mr. Billings at the Second Annual Convention of the Ontario Association of Architects.

the vapor of the breath driven from the nostrils taking at first a downward course; a breath of a fair strength, with the thermometer near freezing point, may be seen by its condensed vapor driven downward and slightly outward for a foot or more.

In this observation, a wind wheel (in air of 26° Fahrenheit), moved rapidly near the body, and steadily at a distance of six inches in front and also at two feet above the head. Notwithstanding this upward current, the breath was strongly marked by condensed moisture fourteen inches below the nostrils, and, would doubtless have been seen further down but for the dissipation of the moisture.

In a room with the air at 65° the same wind wheel was in motion close to the vital parts of the body, but stopped entirely at two or three inches distance from the body or above the head—this was anticipated, because the force that carries the wheel is the rising of the air in consequence of its greater heat and lightness than that of the surrounding air, and is proportioned to the difference of temperature. In order to determine the amount of heat operating to cause the air to rise, a thermometer was placed within the clothing near the vital parts of the body, where it was found to stand at 82°, while the person remained in air at 65°. On going into air at 20° with additional clothing, the thermometer stood at 76°. The air around the body in a warm room, therefore, would rise with a force not far from 17°, while in the outer air at 20° it would rise with a force not far from 56°. Probably the air would rise with a velocity somewhat less than these figures, but relatively they are nearly correct. A more sensitive instrument would have been affected at a greater distance, but the same wheel showed a distinct downward motion of the breath 15 inches below the nostrils in opposition to all the rising tendency by reason of the warmth of the breath and air about the body, and this motion would have been shown at a greater distance by a more sensitive wheel.

Let us now suppose, to be well within bounds, the breath to be moved 12 inches below the face, the downward motion having ceased, the upward motion should then begin, which is to carry the breath up out of the way. This old breath has about one second in which to rise from rest or reverse motion, more than 12" in order to be out of the way of the next inhalation. The difference of temperature necessary to give this movement of 12 inches in the first second, if the breath rises by heat alone, will surprise anyone not familiar with such calculations, it is not less than 180°, that is to say, the breath in order to start from rest and rise 12" in one second through air at 65°, would have to be at a temperature of 245°.

The absurdity to which this calculation and experiment reduce the idea that our breath is carried away from the face by its upward tendency from heat, is increased by the observations which every one may make, that a thermometer at 65° cannot be raised more than one degree by breathing upon it at 9" distance, and that at 10" no effect can be perceived. Under the most favorable circumstances all causes combined are not sufficient to carry the expired breath up out of the way before another inhalation, as may be seen on a frosty day, and it is evident that the air contaminated by the body, if carried upward must be inhaled.

We will consider the circumstances of a large hall of assembly and show the operation of the two systems. Suppose a floor well packed with people at the bottom of a cubical or hemispherical hall: suppose them to have entered at once, the hall being previously filled with pure air; directly the lower stratum of air in which is the audience, becomes contaminated by their exhalations and emanations. Now the problem is to get that stratum of air out of the hall before any of it can come into use again, and to replace it with fresh air of the right temperature.

It is obvious that it cannot be taken out sideways, because then many would have to breathe over again the breath of others—it can be taken only either up or down. If taken up, the fresh air that is to supply its place must enter at the floor from which the foul air rises, for no air will leave the spot till other air is ready to fill its place. In order to lift the whole of the foul air bodily from the floor, it is necessary that the whole floor should be open for the admission of fresh air. Wherever there is a piece of solid floor through which the air cannot pass, there will be a dead space of foul air above it which will not rise with the rest, but will remain to be gradually mixed with the fresh air entering around it. If the dead space is considerable, the whole amount of air required must enter in the limited space of the openings, and the velocity must be proportionately increased. According as the space is reduced and the velocity increased, the air entering has a force that carries it up beyond the place where it is to be used, and mixes it with the foul air passing off, a part of which mixture will return in counter currents and gradually replace the air in dead spaces.

Dr. Reid, of the House of Commons, England, the most scientific and experienced, perhaps, of the advocates of the upward system, seeing this necessity for introducing the fresh air through the whole extent of the floor, had the entire floor made of perforated iron. This was afterwards covered with hair-cloth carpeting, and through nearly its whole extent the fresh air was admitted. The result was, that on account of the rising of dust by the entering air, and still more on account of the uncomfortable draughts brought up against the members' legs, nine-tenths of the floor was covered with sheet lead under the carpet. When the entrance for fresh air was thus limited complaints became so loud both of strong currents and of foulness of air, that the whole matter of ventilation was turned over to Mr. Goldsworthy Gurney, who undertook it on the opposite system of introducing fresh air above and taking out the foul air at the floor.

It is very important in the warming and ventilating that the pure air to be supplied should be of the same degree of temperature and the same amount of moisture as that of an open space in a pleasant time in summer.

With respect to the actual degree of ventilation necessary for health there is great difference of opinion. The following volumes of air in cubic feet per person and minute have been assigned by different experimenters: Dr. Arnot, 2 to 3; Tredgold, 4; Mr. Toynbee, 10; Dr. Bell, 10 to 25; Peclet, according to circumstances, 10 to 20; Peclet, at least 5; Roscoe, (insufficient in Barracks), 10; Roscoe requires at least 20; Dr. Reid, minimum, 10; Dr. Reid requires according to circumstances, 20 to 60; Vierordt, 2½; Hood, ("Warming and Ventilating") estimates the air required for ventilation by the amount needed to take up the moisture from the skin and lungs. The air required for respiration (*i. e.* oxidation) is very much less than that needed to hold in solution the vapor of the skin and lungs which evolve 12 grains of water per minute. If the temperature of the room be at 60° with a dew point at 45°, a cubic foot of air will absorb 2¼ grains of vapor, or in other words, the perspiration from the body will saturate 5¼ cubic feet of air per minute. If, however, we take the dew point down say not to exceed 20 to 24°, then 3¼ cubic feet of air per minute will be required to carry off the insensible perspiration, while for pulmonary supplies ¼ cubic foot will be needed, making a total of 4 cubic feet. In summer the dew point is higher, more air will be required, viz., 5 cubic feet per minute for summer ventilation.

Professor Miles in his report on ventilation of houses and schools assumes that if the temperature of the air ranges from 65° to 70 degrees Fahrenheit, we have the following average results from the respiration of an adult: number of respirations per minute 20; cubic inches of air inhaled and respired 20; cubic inches of air inhaled per minute 400; cubic inches of oxygen each respiration 4; cubic inches oxygen each minute 80; products respired: 1. damaged atmosphere with nitrogen in excess; 2. fifteen cubic inches of carbonic acid gas; 3. three grains of vapor of water.

The surrounding air is vitiated by the mixture of the products of respiration with it at the rate of 2½ cubic feet per minute. The total average loss by the lungs and skin in twenty-four hours is almost 3½ pounds of water, of which somewhat more, ⅔ say 2½, are furnished by the skin, of these 2½ pounds (only 1 6) is furnished by the vital process of secretion by the sweat glands, for the greater part of the moisture transudes through the skin by simple evaporation. For health the body must evaporate a quantity of water within certain limits; the amount evaporated is influenced by the hygrometric condition of the air and by the state of the body itself. The evaporation is increased by muscular action and by a dry atmosphere, it is diminished by repose and by a moist air.

EXTRACT FROM THE REPORT OF A SELECT COMMITTEE ON THE VENTILATION OF THE HOUSE OF COMMONS,

LONDON, PRINTED MAY 31ST, 1886.

"The plan adopted and worked for many years under the superintendence of Dr. Percy consisted in drawing the fresh air into the House and the vitiated air from the House by means of heated shafts in the clock tower and in Victoria tower. By this exhaust process the air in the House was placed under a somewhat lower pressure than the air outside, and a pull thus created which caused the entry of foul air from any accidental source of impurity within reach of this pull, as from closets, etc. Since this plan was established many years ago much progress has been made in the art and science of ventilation, especially in mechanical appliances for the purpose, and by means of these, greater efficiency and certainty, as well as increased economy in working was attained than was possible under the older system.

The great advantage of mechanical ventilation is that as the air is pumped in, a slight excess of pressure exists in the ventilated spaces over that in the outside, and therefore any section of air from impure sources, such as imperfect soil pipes, closets, etc., is avoided. The Committee, for the above reasons, are of opinion it is advisable to cut off the exhaust so that the air pressure may be above rather than below that of the external atmosphere." But it appears by evidence given before the Select Committee of the House of Commons on ventilation, June 1891, that the recommendation in the previous reports had only been carried out to a limited extent, and that the system of extracting the vitiated air at the ceiling is still in operation the witness stated that air drawn from the Court Yard passes by steam batteries by which it is warmed—it then passes down the floor of the house which is perforated all down the centre and in various other parts, there it ascends through the ceiling and passes down four shafts about 700 feet in length to the basement and then horizontally through the basement for a considerable distance and discharges into the Clock Tower where there is a very powerful up cast, which must require a very much larger consumption of fuel than would be necessary if the exhaust were from the floor of the House by mechanical means.

POSITION OF HALLS.

Some adverse criticisms having been made with respect to the House of Representatives at Washington being surrounded by rooms, and not having any contact at the sides with the external air. In a report to Congress the objection is thus met, "It is supposed by many that the inclosure of one building within another, the inner one being the hall, is a serious defect in the construction with a view to equable temperature and a healthy ventilation; on the contrary, it is a great advantage. If the hall approached the exterior wall it would be subject not only to all the internal changes of temperature and elements disturbing the ventilation, but also to all those of the external atmosphere and the weather. Almost every one of the disturbing elements that have been named would be greatly aggravated if the hall approached the exterior. External influences like those of noises, winds, and storms would make themselves felt disagreeably which are now altogether excluded. There is no doubt that the more perfect the ventilation is the more perfect the acoustic properties of the hall will be. A pure atmosphere being favorable to the speaker's health and strength, will give him greater power of voice and endurance, thus indirectly improving the hearing by strengthening the source of sound, and also enabling the hearer to give his attention for a longer period.

In compiling the foregoing remarks, the various reports to Congress by A. C. Stimers, Naval Engineer, General Haupt, L. W. Leeds, Capt. Meigs, E. Clark and others, have been freely quoted, also reports of Select Committee on Ventilation of the House of Commons, London.

After many years of study and experience I am strongly of opinion that the most efficient system of ventilation for halls for the assemblage of large numbers of people is by the introduction of fresh, pure air heated by passing over steam or hot water pipes in chambers and driven and exhausted by the most approved appliances, introducing the pure fresh air at the ceiling and exhausting at the floor, which may be termed the downwards draught and plenum system.

SANITARY PLUMBING.*

By Cesare J. Marani, Grad. S.P.S.

(Continued from April Number.)

That in so far as it lies within our power, the waste pipe system be freed from any tendency to retain decomposing matter, giving off gaseous products known to be detrimental to health, or these very gases when generated elsewhere.

From the mechanical side I should say, have the work done by a thoroughly reliable and competent workman, one who knows and realizes the importance of honest workmanship in connecting pipes, in ventilating traps, etc. To place the work in the hands of an admittedly good man, a thorough mechanic in hims lf, but one who always employs undermen to do his "jobs," and then to rest at ease with the false idea that your share of the work has been performed, and that the workmanship will turn out as desired, reminds me of the story of that simple-minded housewife, who, after placing her marketing of game and fowl on the table of her cottage, and then firmly securing the windows as against the ingress of eagles and other birds of prey, went off leaving the cottage door wide open. During her absence, the fable goes on to say, bears, and other beasts, entered and carried the marketing away.

It is the duty of the architect to determine whether the men actually doing the work are competent or not; and further, he should insist that the work be done by competent men, and competent men only, otherwise all kinds of defects will crawl into the system and prove beyond detection when the work is finished.

Recesses due to badly constructed joints, beads, and strings of solder, or the ends of gaskets in the pipe, all tend to retain filth. Bad connections between vent pipes and traps, destroy the efficiency of the latter. Unnecessary traps, or want of sufficient grade, are again, blunders for which the architect or designer of the plumbing system is alone to blame.

The sizes of the soil pipe and waste branches have also an important bearing on this point. For unless they are so proportioned as to be self-cleansing, the interior surface of the whole system will coat over with a greasy slime, known to give off pestiferous gases ten times more abominable than those found in the main sewer.

Ventilation, while indispensable as a diluter and safe remover of any gases forming or collecting in the system, tends furthermore to arrest, and to a great extent destroy, such gases forming. The free ventilation of the whole system, therefore, demands our most careful consideration. This brings up a point still at issue among leading sanitary authorities:—"The whether a trap should be placed on the house drain before it empties into the street sewer, or not." I am inclined to side with those who h ld that, while there may be some doubt as to the policy of omitting such a trap in cities, for instance like Toronto, where in the first place the main sewers have been ill constructed, and still more badly ventilated; that, even in the case of only tolerably good sewers, such arguments are only valid that advocate the omission of such traps. It is a fact that such traps arrest the flow of the waste liquids along the pipes, and therefore destroy in a measure their scouring properties, besides reducing the efficiency of carriage of the said liquids.

They also end to complicate the system by rendering it necessary to introduce a fresh air inlet pipe, on the house side of their water seals, in order to provide for ventilation.

At the best this additional pipe, when brought a few feet above the ground, certainly does not add to the artistic effect of a building, and may sometimes prove dangerous to children who may be playing in its vicinity. For since we have the pressure of this obstructing trap on the one side, and sometimes a descending column of water in the soil on the other, any gases thus confined between the two, can only escape by this so called "fresh-air inlet pipe."

Besides, I feel fully convinced that the best and most uniform ventilation for our lines of pipes and drains can only be secured when we open one end into the larger street sewer beneath the ground, and the other towards the starry firmament above the roof.

That every part of the plumbing be visible, whenever possible, and conveniently situated as against accidents and repairs.

It is not long since you could not find a single fixture in even the most costly of dwellings, that was not tightly cased in wood. This was particularly so with the water closet. Sanitarians pointed out the dangers to health arising from such a practice, and to-day one can judge of the general improved tone of public opinion on the matter, by just simply looking though any of the numerous descriptive catalogues issued by manufacturers of plumbing fixtures, etc., who, of course, study the demands of the market.

The public taste is certainly tending in the right direction, when marble topped wash basins, supported merely by open brackets or brass legs, and water-closets free from all woodwork save for an oak or mahogany top, are being introduced into the better class of dwellings.

Still we find that certain parts of our system, just as important to the efficient working of the whole, but because of less pretentious appearance than the wash basin and water closets, often seem to have been sadly neglected in the apportionment of the plumbing expenditures. I refer to the all important kitchen *sink*, and servants' hopper.

One often finds that while care and judgment are manifest in the selection and arrangements of the other fixtures of a house, any cheap concern has been accepted to pass for the kitchen sink. But, as if instigated by some secret feeling of doubt as to the justifiableness of such a course, and as if ashamed of the uncanny result, we find that the owner, or architect, has had it securely encased in carpentry.

Not only are the waste pipes, traps, and joints thus cut off from view where they most require watching, but as the dark foul space underneath the sink is invariably utilized for the storage of cooking utensils, mops, rags, old shoes, coal oil cans, scrubbing brushes, boot blackening, grease, and other matter certainly never calculated to aid sanitary conditions.

The same might be said of the servants' hopper, which should be free from all wood work.

It should be placed where a quantity of light and ventilation can be had at all times, and not carefully and gingerly confined to a little cubby hole somewhere beneath the staircase, or in a dark unventilated closet, where it works mysteriously in a mysterious darkness.

A word with regard to the soil pipe in the basement. The best practice of the day is justly tending to do away with the burying of the soil pipe within the house, and underneath the concrete or wooden flooring of the cellar. That this was a pernicious habit it is needless to explain.

Should an obstruction of any kind take place within the house, it might necessitate the tearing up of yards and yards of flooring. And then again, a line of pipes so placed could not be tested and examined as effectually as if raised clear of the floor, and open to view, leaks and other imperfections announcing their presence, and being detected much more readily, in the latter case.

That all parts be of sound material, free from flaws, blemishes, or other defects and of the kind of material best suited for their special purpose.

In the last few years wrought iron has been introduced in the plumbing of buildings, under what is known as the "Durham system of house drainage."

The great advantages claimed by Mr. Durham, a civil engineer, for his system are that "wrought iron pipes are elastic and cannot be broken, and that when lengths are screwed together in a wrought iron coupling, the joint is as strong as any other part of the pipe; furthermore, they will stand up vertically from a solid base to the height of any building without lateral support, and being much lighter are more easy to handle."

Mr. Durham goes on to say:

"By the use of wrought iron-pipes and screw-joints we construct a drainage apparatus within the building, which is gas and water tight as regards the joints; rigid, yet elastic; entirely independent of walls or floors for support, and absolutely invulnerable. As a structure it will last as long as any building will stand, and without any outlay for repairs." The thorough reliability of screw joints, and the uniformity of thickness and strength which can only be secured by the use of wrought iron soil pipes, seem to be the chief points in favour of this system.

Cast iron pipes, when of sufficient thickness, make good soil pipes. This is easily determined by their weight, and the only quality, known on the market as "extra heavy," can be safely recommended.

Even this class of pipe sometimes displays a marked unevenness of thickness on he opposite sides of a cross section, and therefore being in its weakest part no better than light pipe.

The bells on the "extra heavy" have sufficient strength to stand the caulking necessary to insure a trustworthy joint, which is not the case with the lighter class of pipes.

Lead is of course unfit for soil-pipes, and should not be used even for waste pipes when a diameter of over two inches is required. For smaller waste and vent pipes, lead can be used to great advantage, for it bends, cuts, and manipulates easily.

The thickness of any lead pipe, or in other words the weight per running foot, should always be determined with reference to the work it is intended to perform.

Cast lead traps are objectionable, drawn lead being preferable for that purpose.

Traps and pipes made by hand of sheet lead are of course out of date.

Brass is also used in ferrules and in the best forms of traps. It is also used, either polished or nickle plated, for those portions of the plumbing system that lie exposed in connection with the better class of fixtures.

Cast brass traps, are among the very best and most efficient, and to my mind a great improvement on lead traps.

Glass, when used as a portion of a trap, is objectionable, as it is so liable to break by a number of causes.

With regard to the fixtures of this system, I might say that the water closet should be of earthenware or porcelain ware, in one piece, and connected to the soil pipe by the brass flange method. Any of the washout closets are good, though the more recent siphon closets, as for instance the Sanitas, and also such improved hopper closets as the "Trent wash down," are considerably better. For the respective advantages of these I must refer you to works on the subject. Baths and basins should be of porcelain ware. When a bath of this kind should be found too expensive, a "porcelain-lined iron bath" of the Imperial class will answer well; and hoppers and kitchen sinks should be preferably of English brown ware, or Yorkshire ware. Porcelain-lined wash tubs are good, though they do not last like the porcelain ones.

That the whole system be put tightly together in the best approved manner, and possessing uniformity in strength and durability.

This comprises a very wide and important field, for, not only must the mechanical part, *i. e.*, the cutting, bending, fitting, wiping, soldering, caulking, etc. (which go to make the Art as distinct from the Science of plumbing), come under consideration singly; but the whole work must be previously thought out, with a view to uniformity of strength and durability of the entire system. While the most approved practical methods may be understood by the scientist, it takes the practical workman to carry them out in part or in whole, and for this fact a good mechanic is indispensable. For the tightness and safety, then, of our system, we have to depend on the mechanical ability of the men we employ. No matter how scientific and commendable our plans, if the workmanship prove below the mark, miserable or defective, we must expect to meet with disappointment or failure. I therefore fail to see the force of the arguments seemingly based on the

*Lecture delivered before the Engineering Society of the School of Practical Science, Toronto.

assumption that the science is everything, and the art a very secondary portion of our subject.

That this was the tendency among sanitarians in Great Britain, when sanitary plumbing received a fresh impetus some ten years ago, may be seen from the following remarks by S. Stevens Aellyer :

"If I were going to build a house for my own occupation, I should prefer the plumbing work to be done by the man who was more skilled in the science than in the art of his craft—that is to say, I should prefer a poor joint wiper to a clever one, providing the former knew what the latter did not, viz., how to select and arrange the trap, pipes, and fittings, so that they would be 'self-cleansing'; what kind of traps to select, and how to ventilate them so that they would not lose their water seals, how to ventilate the waste-pipes, soil pipes, and drains, so that the air within them should be constantly changed—know, in short, how to execute his work on sanitary principles."

In these days of *specializing* and *high speed*, it would almost be impossible to find a man who might be considered equally competent to lay out both a system of plumbing for you, and construct the same from cellar to attic with his own hands. We do not expect it. We do not want it. But we do insist on the joints being well wiped, the bends properly made, and the bells tightly caulked.

That the whole system be as simple as possible and consistent with convenience, efficiency, and security.

I think this appeals to all scientific minds, though I know of certain plumbers in this town, who, if judged by their works, certainly could not be said to agree with me in this respect.

However, I am glad to notice that there is a strong tendency towards simplification in plumbing work throughout this continent, which will tend to make good plumbing more popular and less costly, and I firmly believe that a judicious use of anti-siphonic traps will prove one of the greatest factors in simplifying the house-plumbing of the future.

While I do not admit that they are preferable in *every* case, and for *all* fixtures, still I will say this, that the better kinds are more trustworthy, and less liable to get out of order than architects and sanitarians imagine, and further, that for certain cases they are undoubtedly the only traps that meet the requirements to any degree.

Owners should be advised against such fads as, for instance, having a basin, or other fixture, placed in some remote corner of the house, and at a considerable distance from any of the main pipes of the plumbing system. Such arrangements greatly increase the number and complication of pipes, not to speak of the cost, and the fact that security is being sacrificed, in a measure, for trifling convenience.

At present the vent-holes in water closet fixtures are made too small. A water closet trap should be vented with nothing less than a 3-in. vent pipe, and running traps under basins, etc., should be vented with vent-pipes at least of the same size as their wastes, and in most cases a little larger diameter is preferable.

Sanitarians seem to forget that while ventilating pipes are useful in preventing the siphoning of traps, their principal work is to ventilate. Experiments have shown that they cannot do this *effectively*, unless they are made large enough.

As sink wastes have a tendency to be too large, we may therefore expect to see, in the near future, the diminution of the diameter of certain wastes, and the enlarging of certain ventilating pipes, and thereby the increasing of the efficiency of both.

That the appliances used be economical, reliable, and adding materially to the comforts of the inmates of the building.

In conclusion, I may say that the number of fixtures in a dwelling should be kept down as much as possible. Not merely from a consideration of economy, but from the more important standpoint of health. The oftener traps are used the better. Where a house has a large number of basins, some may be rarely used, and their traps are liable to evaporate away. Wherever overflow-pipes can be done away with, it is for the better.

Basins provided with the Boston plug, which acts both as a plug and as an overflow waste in itself, are the best fixtures of the kind on the market to-day. Wastes from refrigerators, cistern, safes, etc., of course should never be connected directly to the plumbing system, but all these secondary points are well treated in any of the more recent books on the subject.

After all, the underlying principle of "sanitary plumbing," is to secure such an arrangement of pipes, traps, and fixtures, that any solids, liquids, or gases can readily and speedily find an entrance into the plumbing system, at any of the openings in the house; but that having once gained an entrance, they can never-more return to injure the health of the inmates of that dwelling. When this fundamental principle is thoroughly understood, it should not prove a hard task to determine upon a sanitary system of house drainage.

The Hobbs Hardware Company, London, Ont., will start a bevelling, silvering and plating factory.

Mr. E. R. Burpee, is at the head of a company which proposes to establish granite polishing works at Calais, N. B.

Mr. Peter Nicholson, one of the oldest contractors of the city of Montreal, died on May 3rd from injuries caused by a runaway horse. Deceased, who was seventy-one years of age, was a native of Castleton, Caithness, Scotland. He was a resident of Montreal for thirty-four years.

MANUFACTURES AND MATERIALS

HYDRAULIC CEMENTS—NATURAL AND ARTIFICIAL, THEIR COMPARATIVE VALUES.*

(Continued from April Number.)

The Board of Public Works, or the city engineer advertises for cement. The specifications call for a certain fineness, and so many pounds tensile strain—1 hour in air and 23 in water.

Then up comes the great unwashed army of cement-makers, who, unlike the engineers that sit in judgment over their hard-wrought products, have not yet awakened to the wondrous advantages of association, having no "A. S. C. E." (American Society of Cement Experts), through which to elevate their calling to the dignity and standing it deserves. And so they scramble up to the engineer's office each with his pockets filled with testimonials proving his cement to be the best manufactured in the United States.

And what of the engineer? We notice a peculiar gleam in his eye, that we never observed before. Serenely he surveys the group of uneasy cement-makers before him. He opens the bids, and as usual, the figures are all bunched closely together. The cement-makers are anxious. Not so with the engineer, for with a sardonic smile he vouchsafes the blood-curdling information, that the board had ordered a testing machine.

In the course of time it is announced that the contract has been awarded to Mr. A., as his cement stood the highest in the test. Then another city advertises, and the same operation is repeated, and B gets the contract, because his cement stood the highest in the test. And so with one city after another, and the cement-makers from A. to Z. all get a chance, and all are satisfied, for each has found a place where his cement has tested the highest, thus proving conclusively that each brand was the best.

In our search for the key, with which to unlock the door of discovery of the connecting link, that as we have said ought to exist between high tensile strain and first quality, we have traveled up and down the whole line, commencing with cement containing 50 per cent. clay and 50 per cent. lime, and following along up through its varying mixtures until pure white lime with no clay is reached.

These we have studied under every conceivable manner of manufacture and subsequent manipulation. Studying the varying properties, with all their bewildering and mystifying contradictions; plodding through the thousand and one phrases that are continually being developed in the course of a long experience in the study of the natural cements of this country, no two brands of which are alike in their proportions of lime, magnesia, silica and alumnia; searching the tables of tests made by prominent engineers from time to time; comparing the tables with the analyses of the brands tested; weighing carefully every feature that gave the slightest promise of throwing light on the subject; and now, after all these years, we are compelled to admit that we have not been able to discover the slightest relationship between the high test and good quality. We cannot tell what the future may have in store for us. Some genius who may not have devoted more than his spare moments to the subject, may tell us all about it.

Practical experience teaches that we can find both good and bad cements that will sustain a high tensile strain, and that we can find both good and bad cements that will test low.

Portland cement has not been in use in this country long enough to earn the position it now occupies, but owing to some peculiarity in its molecular construction, it will test higher than our American cements and will get harder. Yet hardness is no evidence of durability; with equal exposure, a flint stone will disintegrade much more rapidly than a soft magnesian lime stone.

But the demand is for a higher testing cement, and the engineer who years ago, used American cements in a sewer or bridge, without a thought of failure and with no signs of failure yet in sight, will incline to the belief that he ought to use a better cement, and so Portland is used in what are called trying places. But the fact that he once used American cements successfully in places just as trying, is dismissed, for he does not care to take any chances of that kind again, and so public opinion has been built up, and it would be a rash man indeed who would dare to stand up against it.

Even the manufacturer of a first-class American cement, who may have grown grey in the business, looking back over the field, calls to mind the work done with his cement. Here is a costly bridge with its piers reaching far down below the surface. There is a tunnel running through the base of a mountain. He recalls the great bridges over the Niagara, the water works tunnel under Lake Michigan at Chicago; the great bridges spanning the Ohio, Mississippi and Missouri; the thousands of miles of railroads with their innumerable culverts and bridges; the sewers in all the cities of the country, amounting in the aggregate to hundreds upon hundreds of miles. With all these marvelous engineering works of the past to look upon, consuming upwards of seventy-five million barrels of natural cement—all manufactured in this country, and none of these works requiring renewal on account of the poor quality of the cement used, yet the manufacturers of this enormous amount of cement are daily reminded that their cement is an article, good enough perhaps of its class, but it is only a common cement at the best.

(To be Continued.)

CANADIAN ARCHITECT AND BUILDER.

VOL. V.—NO. VI. TORONTO AND MONTREAL, CANADA, JUNE, 1892. PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),

PUBLISHED ON THE THIRD SATURDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

14 King Street West, - TORONTO, CANADA.

64 TEMPLE BUILDING, MONTREAL.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

A DICTIONARY of Architecture has just been published which has been in course of preparation in England for more than forty years. With the exception of some twenty copies the edition which has been published has been sold to subscribers. As the work is said to be most authentic and complete, it is hoped a new and cheaper edition may be published.

THERE died in one of our Canadian cities recently a gentleman who delighted to call himself the friend of the widow and orphan. His will, which has just been admitted to probate, disposes of property valued at nearly half a million dollars, yet strange to say, not a single dollar thereof has been devoted to the benefit of widows and orphans or any other benificent object. It is to be regretted that so few bequests are made by men of wealth in Canada for charitable and educational purposes. It is true that some very handsome endowments have been made by wealthy citizens of Montreal to institutions in that city, notably the Royal Victoria Hospital and McGill University, but the number of philanthropists is by no means as large as it ought to be.

A BY-LAW respecting the construction of building scaffolds has recently passed the Toronto City Council. The by-law simply indicates the materials of which scaffolds should be built and stipulates the method of their construction. The City Commissioner is empowered to prosecute any person who may proceed with the erection of buildings using scaffolding which is not constructed in accordance with the by-law, or in the event of finding a scaffold which in his opinion is unsafe, any person who, after due notice, neglects to make the same satisfactory. The penalty for violation of the by-law is not to exceed $50 for each offence. It will be observed that the proposal urged upon the Council some months ago for the appointment of an expensive corps of scaffold inspectors has wisely been disregarded. The by-law in its present form will not be likely to prove very objectionable to builders.

AT the time of going to press, the city council of Toronto had not appointed a City Engineer. Unless Mr. Jennings could be induced to again take the position at his former salary, we doubt whether the Council will be able to appoint a more satisfactory man than Mr. C. H. Rust, at present acting City Engineer. Mr. Rust has been connected with the Engineering Department of the city for upwards of fifteen years. For several years he has had the entire charge of the construction of sewers, and in this capacity has done satisfactory work and proved himself to be possessed of the requisite executive ability. If Mr. Rust has given the city good service in the past, and is capable of filling the larger position, it would be unfair to give the appointment to an outsider. Should circumstances occasionally arise calling for engineering experience and ability of the highest order, the temporary assistance of an expert consulting engineer could be obtained. Such occasions are not likely to be frequent, and consequently should not involve large expense.

WE learn from the *Brickmaker* that there is much indignation expressed by Hudson River brick manufacturers over the action of the United States government in stopping French Canadians from going over the line to work on the brick yards under the Contract Labor Law. It has been the custom for years for these men to work in the brick yards during the summer, over 1,000 of them being employed every year. They spend most of their wages in the States, and before going home to work in the woods in winter lay in their supplies. The effect is, the manufacturers say, to cripple the yards, without benefiting the country, for the places of these men are gradually being filled by Arabs from the Holy Land who will carry the money paid them out of the country. The Alien Contract Labor Law, and some other measures recently enacted by the government of the United States, have to a large extent brought the statesmanship of the Republic into contempt before the world. Without attempting to detract from the many admirable characteristics of the American people, it can truthfully be said that as a nation, the United States has stooped to petty meannesses which no other country of importance on the face of the earth would be guilty of. In some instances the self

respect of the nation has been dragged in the dust by politicians anxious to make themselves and their party "solid" with certain vote controlling elements.

THE removal of St. Andrews Church, Toronto, from its present situation, at the corner of King and Simcoe Streets, to an up-town location, has been decided upon. No doubt, from the standpoint of the church's interest, the decision is a wise one. The building is situated at too great a distance from the modern residential part of the city, and in consequence, some of its members are forced to attend other churches. The removal of this church will deprive the city of a piece of street architecture which for nearly twenty years has stood an object of pride to the citizens and of admiration to visitors. The site on which the building stands was deeded to the trustees on the condition that a church would be erected thereon within a fixed period. When the limit of time had nearly elapsed a competition was held with the object of securing suitable plans for a building. The plans submitted by Mr. W. G. Storm, of Toronto, were chosen, and the building erected therefrom at a cost of $100,000. An illustration of the building, which is in the Norman style, is published in the present number. Tenders are now being asked for taking down the church and for its re-erection on a new site. It is estimated that the depreciation in the material would amount to about twenty-five per cent.. It is not the intention we understand in re-erecting the building to make any alteration in the design. It is to be hoped that proper care will be taken to select a site which will display to not less advantage than at present its beauty of design.

CANADIANS should make the most of the opportunity afforded by the approaching World's Fair to make known to the world the capabilities of this country and its people. We are pleased to notice that in agricultural, manufacturing and other lines, steps are being taken in this direction. It would seem pertinent to enquire what will be done to show the status of Canadian architecture. The desirability of making a Canadian architectural exhibit will hardly be questioned. Such an exhibit would tend to attract to Canada persons of refinement, many of whom have been imbued with prejudice against it in consequence of misconception regarding its climate and the status of its civilization. Canadian architects should lose no time in preparing for this exhibit designs which should exemplify their best talent. They should be sufficiently patriotic to devote whatever time and money may be necessary for this purpose. So far as time is concerned, the prevailing dullness has left many members of the profession with abundance of leisure which could not be used to better advantage. We are pleased to be informed that some prominent members of the profession in Toronto have already decided to exhibit their work either individually or in conjunction with other exhibitors, as circumstances may direct. It will of course be necessary to decide the conditions under which the exhibit should be made; that, however, is a matter of future arrangement. As the preparation of suitable drawings may be presumed to occupy several months, it is very desirable that a commencement should be made at once.

A COMPETITION was instituted last year for designs for an Episcopal Cathedral to be erected in Victoria, B. C. The limit of cost was fixed at $150,000, a sum very inadequate for the purpose. The competition closed on the 31st of December last. The competitors numbered fifteen or sixteen, and were almost equally divided as between English and Canadian architects. Three prize were offered, the first being $750 and 5 per cent commission on the cost of carrying out the work; the second, $500, and the third $250. Sir Arthur Blomfield was appointed to judge the designs. His award has just been announced. The first prize is given to Messrs. Evers & Keith, of Victoria; the second and third prizes will, it is said, go to two of the English competitors whose names have not yet been disclosed. The Canadian competitors, being situated at such a distance from the place of award, had two weeks less time than their English competitors in which to prepare their drawings. In consequence, some of the Canadian designs had to be forwarded in an incomplete condition. The accepted design is said to be in the style of the XIII century. The total length is 236', height of spire, 275', internal height of ceiling of nave 72'. The cross has been retained as the basis of the plan, the transepts being shallower than in most of the old examples. The tower has been placed in the centre of the west front. On the east side of the east gable rise two turrets 93' in height. The walls will be of stone with cut stone finish, ceiling of cedar and roof of slate. The total seating capacity is 1468, 3'3" x 1'1½", being allowed for each person. The enterprise may be regarded as an English rather than a Canadian one, as it is understood that two thirds of the cost will be defrayed out of subscriptions of well known English philanthropists.

SCIENTIFIC men and the general public have indulged the belief that of late sanitary science has been making satisfactory progress. In his paper on "The Free and Liberal Ventilation of Sewers in its Relation to the Sanitation of our Dwellings," read before the Royal Society of Canada, on May 31st last, Mr. Chas. Baillairgé, City Engineer, of Quebec, puts himself squarely in opposition to some of the most important doctrines of modern sanitarians. He says: "A host of unemployed would-be-scientists in each city, are constituted a 'Board of Health,' elect a President, Vice-Presidents, Secretaries, Treasurers; appoint health officers, inspectors, etc., and this galaxy of hygienists, to give themselves an air of public usefulness, prove over zealous in clamoring against the falsification of alimentary substances, in advocating and filtering of water, in conjuring up microbes, bacteria and contagious diseases, in battling for vaccination, disenfection, ventilation and the like. They fancy they are serious and in the end become so, and would convince people that a thousand precautionary measures are at present indispensable, of which no one ever dreamed in the past, and without in any way suffering therefrom." And again: "let me say in one word, to have done with these preliminaries, and show that in many cases, the evil is not nearly as great as it is said to be, that while we are crying out for ventilation, nine tenths of the human race do without it and appear to be none the worse for ignoring it. A thousand precautions are sought to be enforced in the drainage of our houses. Thousands of towns and villages, the wide world over, ignore the thing entirely and live quite as long as those who at such great cost give themselves the luxury of sanitary modes of removing their excreta; and during epidemics, as during normal times, there is no more, no less sickness, there are no fewer, no less deaths in the one case than in the other." These opinions, from which most persons will feel inclined to dissent, are to some extent modified by those following, in which the importance of providing for the exclusion of sewer gas from dwellings is discussed.

CHARACTERISTICS OF ARCHITECTURAL STYLE.

BY G. F. STALKER.

SINCE the Queen Anne revival, and to a large extent on account of it, there has been more energy and individuality displayed in the architecture of Great Britain, her colonies and America, than has been the case in any similar period of the world's history. It is a noticeable fact at the same time, and probably also attributable to the same cause, that during this time style in architecture has got somewhat mixed. The misfortune in regard to the Queen Anne revival was not on account of any lack of genius on the part of the architect who was the chief mover in it, but that the Queen Anne style (if style it may be called) was essentially debased and impure. During the latter part of the reign of Queen Anne, when the kind of building which bears her name was in vogue in all its pristine impurity, architecture was at as low an ebb as it well could be. The knowledge of art, in any of its branches, had departed; but the belief that Rome was the mother of art and Italy its home, possessed the minds of the people; and consequently nothing that had not a smattering of Roman or Italian art would pass muster. And, as generally happens under such circumstances, the least pure features of the Italian renaissance, with its broken backed, curved or twisted tympani, its disproportioned mouldings and obtrusive carving, were copied and stuck on to buildings in England, without any regard as to fitness or congruity. And in these latter times the absurdities, and the outgrowths of the ignorance displayed in the days of Queen Anne have come to be looked upon as quaint, piquain, or artistic architectural adornments. But there is properly speaking, no style in them. A cool headed architectural critic would pass over the Queen Anne period without the slightest notice. A much better revival and one more likely to be lasting, is the Norman. This is often but most erroneously called "the modern Romanesque," but there is nothing Romanesque in it, excepting that the semi circular arch is used, and this was also the dominant feature of the Norman. Everything else in this revival is peculiarly Norman, and consequently it is based upon a style of great purity. Herein, then, lies the great difference between the two. In the latter, modern architectural expression has been founded upon a distinct language, in the former it rests on a poor kind of patois. These two revivals are noticed here merely to show the effect that a clear knowledge of architectural style will have upon any attempt which may be made to found a new development, or departure, in architecture, upon any style which has previously existed. To take as a model the class of buildings that were erected at a time when architectural knowledge was meagre, and the outcome of it in consequence debased, may create a fleeting fancy, but will have no lasting beneficial effect on architecture. While, on the other hand, to take as a model a period when architecture was studied and practiced as a fine art, the result cannot fail to have a good and permanent influence.

The question of inventing a new style of architecture is often raised by unlearned men; and architects are often taunted with the fact that they are unable to accomplish this object. But then no man ever did invent a style of architecture or a language. They are both the growth of centuries, having in them the distinctive marks of the people amongst whom they have sprung up, and have been developed and perfected, but bearing also upon them traces more or less definite, of international influence. It is, therefore, no disgrace to a young country like Canada, that she has not yet reached that fulness of architectural stature, to claim for any of her buildings a truly

and distinctly national character. At the same time, the tendency of architects in the Dominion is happily in this direction. And this being, the case a consideration of the characteristics of architectural style may not, at the present time, be deemed inopportune or unimportant. It is a matter of uncertainty to fix the dates of some of the older buildings of the world, or even to be very positive in asserting what nation has the first claim to have had a national style. On these points the doctors disagree, but the majority of writers are of opinion that, in the architecture of Egypt, we are taken further back in the history of the world, than in that of any other nation. It is now known, beyond question, that some of the pyramids were erected at least 3000 years B. C., and when the great mechanical ingenuity displayed in these wonderful structures is taken into consideration, together with other evidences of the high state of civilization the Egyptians had attained at that early period, we are absolutely at a loss to ascertain how far back their history as a nation extends. For the purpose of this paper, however, it is sufficient to start with the pyramids, as the earliest architectural monuments known to us in the world.

In these, as in all other buildings which have been discovered in Egypt, the great predominating feature is mass. The Egyptians were essentially builders, and they built for eternity. It is nowhere found in any of their buildings, not even in the tombs or temples, that the details are emphasized in such a way as to detract from the massiveness of the whole composition. Simplicity and stability were with them of the first importance, and where ornament and color were introduced, their introduction did not in any way lessen the sombre grandeur, or the eternal purpose of the structure. But being kept in subjection and painted or carved with remarkable fidelity and truth, they served the double purpose of affording relief to the eye, and giving scale to the buildings.

In many of the chambers of the pyramids, and particularly in the tombs and temples, color was freely used; not as an after thought, (as decoration is arranged for in our own day) but as an essential part of the original design. And though the colors were always brilliant and lustrous, the general harmony was maintained so perfectly that the effect was always pleasing. The subjects chosen for these mural paintings were generally scenes from their daily life; and so from these we have a more accurate history of this people than we have of many nations that came into existence when ancient Egypt had almost or altogether disappeared. Sculpture also, was very largely used, and wherever it was applied, like painting, it formed part of the original conception. And these sculptural representations may always be taken to be most faithful portrait. No flattering touches were permissible. The sculptors were required to adhere most scrupulously in every line and feature, to an exact representation of the original. Some writers on Egyptology even go so far as to assert that rigid accuracy both in painting and sculpture, wherever the human form was concerned, was not so much an artistic as a religious necessity. In the more strictly architectural ornamentation of their columns, doorways, cornices and other portions of their buildings, however, although their ornament was generally based upon natural objects immediately at hand, it was invariably conventionalized. And when color was applied in these cases, it was so arranged as to contribute to the harmony of the whole composition.

The remarks which have been made have reference, as any one may see, to the great public buildings of Egypt. But with regard to the domestic architecture of the country, very little is known. Even from the solitary example now remaining at Medinet Habou (this being a royal pavilion) we can form only a faint idea of the general character of their domestic work. But we can well imagine that the people who erected, with such taste and skill, pyramids, temples, tombs and palaces, which were intended to defy the destructive forces of time, must have exhibited the same refinement in their domestic work, although they may have built their houses with more perishable materials.

A very singular and noticeable fact with regard to Egyptian architecture, is the continuance of the national features and characteristics of the style right on until the time when it may be said that Egypt ceased to build. The Egyptians were conquered by the Greeks and afterwards by the Romans, two great building nations, but, unlike any other people who fell under their domination, their influence on the architecture of Egypt is nowhere visible. Many great and notable buildings were erected both under the Greeks and the Romans, but they were carried out in every detail just as if neither Greek nor Roman had ever seen Egypt. This is very strong evidence that those two great peoples saw in the architecture of the country they had conquered, its absolute suitableness to that country, for, though they both imitated and grafted on to the styles which bear their names, features essentially Egyptian, they left the architecture of the country, during the period of their occupation, altogether untouched.

Following the Egyptian period, in point of antiquity, we reach the Chaldean, in which, however, must be included the Assyrian and Persian styles. The oldest buildings of these people so far as can be ascertained, date back to about two thousand five hundred years before the Christian era. Unfortunately the materials used were mostly of a very perishable nature, such as wood and sun-dried bricks, so that the remains of them are, in most instances, nothing more than heaps of shapeless ruins. But during the reigns of the Assyrian and Persian monarchs, more durable materials were manufactured or imported, and then many palaces and a few temples were erected of gigantic dimensions, and in all the gorgeousness of eastern show and splendour. Symbolism and allegory, having always been the most natural expression of the mind of the western Asiatic, are, in the Chaldaic buildings, employed to their fullest extent. As a necessary consequence they are more decorative than architectural, in the strict sense of the word, always gorgeous, though sometimes having a leaning to the barbaric. Some of the architectural forms they invented, were, however, turned to good account by the Greeks, and are better known to us in their European than in their Asiatic dress. At the same time the remains which have been, and which, it is to be hoped, will yet be discovered and explored (such Nineveh, Persepolis, etc.) must always be of vast importance and interest, although more to the historian than to the architect.

Unfortunately, the Jews had no style of architecture whatever that they could call their own. The greatest buildings that were erected in Judea, even during the time when they endeavoured to mark their prosperity and importance on the history of the world, were the conceptions of foreign architects, and the execution of foreign builders. Probably this is due to their too literal interpretation of the second commandment. But whether this is the case or not, the fact remains the same, that there is nothing essentially Jewish to be found in the whole history of architecture.

ONTARIO ASSOCIATION OF ARCHITECTS STUDENTS EXAMINATIONS.

In response to a number of requests we publish below the examination papers used in the above examinations:—

Practical Knowledge of Building Trades.

FINAL.

APRIL 5TH.

MR. E. BURKE, *Examiner.*

NOTE: *120 Marks will be the maximum number possible to be obtained and 60 per cent. the minimum to pass.*

Values.

10 1. Name a simple method of "squaring" in laying out the lines for the erection of buildings. What are "batter boards"? and what is their use?

15 2. Draw to a scale of ½" to the foot, a section of a cellar wall of rubble stone 18" thick, showing proper construction, with footings and methods of keeping the walls dry and of removing water of soakage and springs. Write explanatory descriptions.

15 3. Draw to scale of ½" to the foot, to carry an iron column, a brick pier 2' 3" square, 8 ft. high, with double footing course. Show also plans of two consecutive courses of the brickwork. Wood beams 10"x12" will rest upon two sides of the pier, one foot below the top, in such a manner as not to weaken it.

15 4. In constructing a heavy tower wall of stone, in connection with a lighter stone wall abutting upon the same, what precaution should be taken to prevent unequal settlement which might occur even when the footings are properly proportioned to sustain the superimposed load.

12 5. What is underpinning? and how done? Give explanatory sketch. How would you support a brick wall when inserting a breastsummer? Show sketch with explanatory remarks.

12 6. Indicate the construction ½ size of the joint of an 8" cast iron pillar of x section set upon a cylindrical pillar of cast iron 9" diameter. The latter also carries two beams 8"x12".

12 7. Draw ½ size proper method of superimposing wood posts carrying beams, so that the latter may burn or fall out without endangering the whole building. Show also connections of beams to walls with the same object in view.

15 8. Draw section to ¼ scale of a Queen Bolt Composite roof truss of 50 ft. span and pitch of 30 to 40 degress. Show details ½ size. Indicate parts in compression and tension.

20 9. Indicate construction of iron floor beams and posts showing method of fire proofing.

15 10. Show approved construction of a first class veneered door. Show to an inch scale a horizontal section of a boxed window frame with inside folding blinds in boxes.

10 11. Describe and sketch two methods of forming valley and hip flashings. Also method of flashing a slate roof of ½ pitch at a parapet wall.

15 12. Describe three coat plastering, mentioning points in regard to each coat. How should successive coats of paint be treated to gain a proper surface. Show a section of the leads in lead glazing and method of inserting and holding glass.

Strength of Materials.

FINAL.

NOTE: *100 marks count a full paper.*

Values.

15 1. What would be the proper Form of Cross-Sections for a Beam of (*a*), cast iron; (*b*), wood; (*c*), rolled steel; giving your

reasons in each case. Explain the circumstances governing the selection of a factor of safety in each case.

15 2. Explain fully what is meant by the following terms : (*1*), Beam ; (*2*), Short Post ; (*3*), Long Post ; (*4*), Cantilever ; (*5*), Strut ; and (*6*), Tie-rod.

10 3. Explain at length what is meant by (*a*), Shearing Force ; (*b*), Bending moment at a vertical cross-section of a beam.

10 4. How are the Normal and Shearing Stresses distributed over the vertical cross-section of a uniformly loaded horizontal wooden beam.

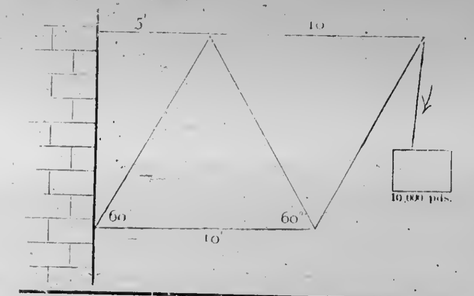
15 5. Explain the principle governing economy of material in bolts and rivets. Find the pitch of the rivets in a plate butt-joint, with a pair of cover plates, double rivetted in terms of the diameter of rivet and thickness of plate.

20 6. What is meant by the terms : Modulus of Elasticity and Limit of Elasticity. Explain fully.

10 7. State clearly the various conditions upon which the strength of posts depends which are long enough to be liable to flexure.

15 8. State and explain the equations of equilibrium for forces acting on a rigid body in one plane.

20 9. Calculate the Stresses in the following truss : (*a*), Analytically ; (*b*), Graphically.



Structural Ironwork.

SECOND INTERMEDIATE.
APRIL 6TH.
MR. E. BURKE, *Examiner.*

NOTE : *100 marks will be the maximum obtainable and 50 per cent. the minimum to pass.*

Values.

10 1. Draw a section ½ full size of a flitch-girder, the timber for which was taken from a piece of 10"x12" stuff. Write description and comments.

5 2. What is the best description of iron for beams? Give reasons.

10 3. Draw a section ½ full size of a cast iron lintel or beam 8" deep and indicate portions which are in compression and which in tension.

10 4. Draw a section ½ full size of a rolled iron girder 12" deep. Show connection of 9" wrought iron beam, both the bottom flanges being level.

10 5. Draw a section to 1" scale of a one and one half brick wall carried on I beam.

12 6. Indicate by a sketch ½ full size such a method of anchoring a 10"x12" wood beam to an 18" brick wall, that the wall will not be pulled over should the beam drop out by burning or otherwise.

10 7. Draw a section to scale of cast iron columns of **H** & **X** pattern and name the parts, with comments.

10 8. Draw section ½ full size of connection of a 9" diameter cast iron column to cap and base plates and name the parts, with comments.

10 9. Draw sections ½ full size of 8" diameter, rectangular and octagon columns built up from rolled iron plates or bars.

15 10. Draw to a scale of 4 ft. to the inch an iron roof truss of ¼ pitch 25 ft. clear span between brick walls. Indicate members in compression and tension.

12 11. Draw to a scale of 4 ft. to the inch a trussed breastsummer formed with 4 pieces of 3x12 joisting, having a clear span of 15 ft. and a space of 2 ft. from top of beam to underside of window sills above.

12 12. What is understood by the terms washer, nut, upset ends to tension rods, torsion, core, cold shot. Draw or describe.

History of Architecture.

FIRST INTERMEDIATE.
THURSDAY, APRIL 7TH.

NOTE : *The Candidate is expected to answer three of the following questions. Drawings are to be neat and to a scale of not less than ½ an inch to 1 foot but they are not required to be finished. The scale used must be mentioned.*

1. Sketch, in outline, the Orders of Classic Architecture ?
2. In what country was the Arch first used as a feature in Architecture ?
3. Name the various styles of Architecture since the introduction of the Arch down to the present day.
4. Describe and illustrate by sketches the leading features of each of these styles.
5. Give an approximate date for each of these styles.

SECOND INTERMEDIATE.
THURSDAY, APRIL 7TH.

NOTE : *Drawings are to be in outline only, neat and well arranged and are not required to be finished. The scale should be not less than ½ an inch to the foot. The scale used must be mentioned.*

1. Draw the Grecian Orders.
2. Draw the Roman Order.
3. What do you understand by the term Romanesque Architecture.
4. Illustrate by drawings the characteristics of Norman, Early English, Decorated and Perpendicular styles of Architecture.

FINAL.
THURSDAY, APRIL 7TH.

NOTE : *The Candidate is expected to answer questions Nos. 4, 8, 9, 10, 14. Additional marks will be given for additional answers. Drawings are to be in outline only and are not required to be finished. The scale should be not less than ½ an inch to 1 foot and must be mentioned where used. It is to be borne in mind that it is not the drawing so much as what the drawing indicates of the Candidate's knowledge, that is required. But neatness of drawing and good arrangement will be taken into consideration.*

ANCIENT ARCHITECTURE.

1. What country may be called the birthplace of Architecture.
2. Through what countries is the history of Architecture to be traced prior to the rise of the Greeks as a nation.
3. Give an outline of the history of Architecture in these countries.

NOTE : *The Candidate is expected to answer one of the above questions.*

GRECIAN AND ROMAN.

4. Name and draw in outline *only* the Orders of Greek Architecture and give an approximate date for each.
5. Draw in outline only the plan and front elevation of a Greek Temple in any order.
6. Explain illustrating by sketches the development of the Ionic Capital.
7. Mention one Greek Temple in *each* Order.
8. Draw the Roman Order.

ROMANESQUE.

9. Sketch the leading characteristics of Romanesque Architecture.

GOTHIC.

10. Sketch a portion of a nave in Norman Early English Decorated and Perpendicular giving the date of each style.
11. What is the practical use of the flying buttress and of the pinnacles ?
12. What is "Flamboyant" Architecture ?
13. What do you understand by Renaissance Architecture ?
14. Describe the main characteristics of the style you have chosen illustrating them by sketches in outline. Give a portion of the plan of a building in this style, sufficient to show the characteristics ; give a section of the roof shewing the form of vaulting, shew the form of the windows, arcading and any other feature specially illustrative to the style.

Mouldings, Features & Ornaments.

FINAL.
APRIL 7TH.
S. H. TOWNSEND, *Examiner.*

NOTE : *150 marks will be considered a full paper.*

Values.

15 1. Show by a diagram how you would arrive at the entasis of a Doric Column.

20 2. Sketch a Triglyph, and show in what way the Greek and Roman examples differ.

25 3. Draw to half inch scale a Greek Conic Capital, and sketch some of the ornament to a larger scale.

15 4. Sketch a "trussed rafter" roof.

15 5. What are Cusps ? during what period were they first introduced. Sketch two examples, one of early and one of late date, and point out the main points of difference between them.

30 6. What are the general characteristics of the mouldings of the period you have sketched, give examples showing how they differ from the periods immediately preceding and following.

20 7. Sketch to a scale of ¼ of an inch to the foot, one of the buttresses against the side wall of an Early English Church, to be 21 in. wide on face, to project 36 in. at the base, and to have three weatherings. Height from the ground to the underside of the eaves cornice twenty feet.

10 8. What do you understand by plate-tracery ? In what styles was it used. Give examples.

15 9. Sketch some foliated ornament in the style you have selected.

25 10. Sketch two examples of string courses in the Norman, Early English, Decorated and Perpendicular styles. One example in each style to be placed under the ground floor windows of a college building and the other at a height of twenty feet from the ground over the main entrance doorway.

30 11. Sketch a doorway in the style you have selected, giving Plan, Elevations, and section through jamb and head.

Algebra.

FIRST AND SECOND INTERMEDIATE.

NOTE : *100 marks will be considered a full paper.*

Values.

15 1. Simplify

(*a*) $$\frac{x}{1-\dfrac{x}{1+x+\dfrac{x}{1-x+x^2}}}$$

(*b*) $$\frac{a^2}{(a-b)(a-c)}+\frac{b^2}{(b-a)(b-c)}+\frac{c^2}{(c-a)(c-b)}$$

(*c*) $$\frac{x+y}{y}-\frac{2x}{x+y}+\frac{x^3-x^2y}{y^3-x^2y}$$

15 2. Two numbers differ by two. Show that the difference of their squares is twice their sum.

20 3. Solve the equation $ax^2+bx+c=o$. If α, β are the roots of this equation prove $\alpha+\beta=-\frac{b}{a}$ and $\alpha\beta=\frac{c}{a}$

20 4. Solve the equations :

(*a*) $x-y=1$
$xy=12$

(*b*) $$\frac{x+3}{2}-\frac{x-2}{3}=\frac{3x}{12}+\frac{5}{4}$$

15 5. Factor :

(*a*) $a^2+b^2-c^2-d^2-2ab+2cd$.

(*b*) $a^2+9ab+20b^2$.

(*c*) $bc(b-c)+ca(c-a)+ab(a-b)$.

20 6. State and prove the rule for finding the Highest Common Factor of two numbers.

10 7. Find the Least Common Multiple of x^2+2x-3 ; x^3+3x^2-x-3 and x^3+4x^2+x-6.

15 8. In a mixture of wine and water the wine composed 30 gallons more than half of the mixture and the water 10 gallons less than a third of the mixture ; how many gallons were there in each ?

Trigonometry.

FIRST AND SECOND INTERMEDIATE.

NOTE : *100 marks will be considered a full paper.*

Values

15 1. (*a*) Define an angle according to the usage of Plane Trigonometry.

(*b*) Define the common units of angular measure.

(*c*) Express in sign and magnitude in any two of the units, the angle described by the minute hand of a clock between the times 9h. 05m. and 11h. 25m.

20 2. (*a*) Explain fully the meaning of $\sin A$, $\cos A$ $\tan A$, and $\sec A$.

(*b*) Discuss the changes in them as A changes from o° to 360°.

15 3. Prove the foll.—

$$\tan A=\frac{\sin A}{\cos A}$$

$$\sin^2 A+\cos^2 A=1$$

$$\sin(A-B)=\sin A\cos B-\cos A\sin B$$

10 4. Express the other trigonometrical ratios in terms of the tangent.

15 5 Prove the foll.

$$\sin(\alpha+\beta)\sin(\alpha-\beta)=\cos^2\beta-\cos^2\alpha$$

$$\sin A=2\sin\frac{A}{2}\cos\frac{A}{2}$$

30 6. What is the logarithm of a number ? Of what use are logarithms ? Prove the statements you have just made.

15 7. Prove $\frac{\sin A}{a}-\frac{\sin B}{b}=\frac{\sin C}{c}$

15 8. Given $a=47.97$, $b=54.23$ and $A=57°\ 34'$. Find B, c and C.

NUMBER—	MANTISSA	RATIO	L
5423	.734240	sin 57° 34'	9.926351
4797	.680970	sin 72° 35'	9.979618
		sin 72° 36'	9.979658
4344	.637890	sin 49° 50'	9.883191
4345	.637990	sin 49° 51'	9.883297

Euclid.

FIRST AND SECOND INTERMEDIATE.
PART 1.

1. (*a*) Triangles upon the same base, and between the same parallels, are equal to one another.

(*b*) E is a point in the side AC of a triangle ABC. Construct a triangle $ECHD$ equal to ABC.

2. If a straight line be divided into any two parts, the square on the whole line is equal to the squares on the two parts together with twice the rectangle contained by the parts.

3. The angle at the centre of a circle is double of the angle at the circumference subtended by the same arc.

4. The opposite angles of any quadrilateral figure, inscribed in a circle, are together equal to two right angles.

FIRST AND SECOND INTERMEDIATE.
PART 2.

5. If a side of any triangle be produced, the exterior angle is equal to the two interior and opposite angles, and the three interior angles of every triangle are together equal to two right angles.

6. In any right angled triangle the square which is described on the side subtending the right angle is equal to the squares described on the sides which contain the right angle.

7. To describe a square that shall be equal to a given rectilinear figure.

8. The bisections of the three angles of a triangle meet in one point.

Foundations.

FINAL.

Values.

10 1. Name one of the best soils for building upon. Is it safe to build upon a clay soil ; state your reasons for the answer you give.

11 2. In building upon a soil which has not level strata or which has portions of clay or loose gravel, what should be done to prevent uneven settlements.

15 3. Where the foundations of a building are not at the same level what means should be taken to prevent uneven settlement.

20 4. If you were putting in the foundation of a building and came upon a soft piece of ground what would you do to obtain a good foundation and prevent uneven settlements ?

20 5. What is meant by the detached pier system of foundations ; when should it be adopted and what are its advantages ?

20 6. In putting in foundations for a building what means would you take to prevent uneven settlements on the part of the supporting soil.

15 7. What are sand piles and under what conditions is it advisable to use them ?

10 8. What would be safe load to place upon a good hard clay soil ?

20 9. What should be done to make a safe foundation where the soil is running sand ?

10 10. Enumerate some of the different forms of piles.

20 11. How would you obtain a large surface support for a building where it is impossible to obtain such a support in the ordinary way by projecting the footing courses.

20 12. Is it advisable to use inverted arches in foundations ; if so under what conditions ?

20 13. State the proportions of a good concrete for filling trenches under foundation walls.

10 14. Should concrete be placed in the trenches or should it be thrown in from a raised platform.

Architectural Jurisprudence.

FINAL.
APRIL 7TH.
S. H. TOWNSEND, *Examiner.*

NOTE : *100 marks will be considered a full paper.*

Values.

20 1. The penalty clause in contracts as it is usually termed, provides that in the event of the Contractor's failure to complete the work, or building to be executed, within the stipulated period he is to forfeit and pay to the employer a specified sum per day or per week, for each and every day or week as the case may be which shall elapse between the stipulated and actual date of completion. The sum of money so forfeited by the Contractor is sometimes spoken of as a "penalty," although in most contracts it is expressed to be as "liquidated damages." Distinguish between these two terms, and give a simple illustration of the difference.

25 2. Does the approval by the client of the drawings and specifications estop him from afterwards alleging that the Architect has failed to exercise proper skill in the preparation of these documents ? If so, to what extent ? and in regard to what matters ?

20 3. What are "torts ?" Do you know of any law or rule of the courts in regard to tort-feasors, liable to effect the liability of an Architect to parties other than his client ?

25 4. State what you know of the responsibilities an Architect incurs in the event of the failure of buildings constructed from his drawings and under his supervision, and say to what extent these responsibilities are shared by the builder and owner.

10 5. State what you know of the relative effect of progress and final certificates.

30 6. A contract provides that the certificate of the Architect shall be a "condition precedent" to payment, and that his decision shall be final, and further that the contractor must obtain written orders signed by the Architect for extra work before such work is commenced. (*a*) What is meant by a condition precedent? (*b*) If the Architect includes in his final certificate extra work for which he is not given a written order or work which has not been properly executed, must the proprietor pay the full amount certified for? If so, why so? If not, why not? (*c*), What will be the effect to the builder if the Architect refuses to grant him a final certificate. 1 Because he honestly believes the work to be improperly done, when as a matter of fact the work is done in a manner that would be accepted by another Architect. 11 Because the proprietor told him he had not the money to meet a certificate, and induced him to delay granting the certificate in consequence.

20 7. To what extent has an Architect power to order changes in the work shown by the drawings and specifications? If for instance the drawings and specifications showed that the foundations were to be piled, and the contract provided that the contractor was to make such additions or omissions as the Architect directed, and the Architect finding piling unnecessary directed the builder to build the building without piling would the court recognize this order? Or if the Architect considered a wall specified to be built of brick would be better if built of stone, would he be justified in ordering the change without the express assent of his client? If he did order it, without such consent, would the court recognize the order?

Heating and Ventilation.

FINAL.

Values. HEATING.

25 1. Name the different ways in which heat may be transmitted and explain clearly how heat is given off in each case.

30 2. (*a*) State the advantages and disadvantages of hot air heating.

(*b*) State the advantages and disadvantages of hot water heating.

(*c*) State the advantages and disadvantages of steam heating.

20 3. In what position should a hot air furnace be placed in relation to the rooms to be heated?

20 4. What precaution should be taken in the running of the hot-air pipes so that hot air may be carried equally to the different rooms on all floors?

5 5. What is the average temperature of the surface of a hot-water radiator when the system is working properly on a cold day?

25 6. State the reason why a hot-water plant cannot be piped similar to steam. That is, what precautions are necessary to ensure that all radiators may obtain an equal supply of water?

20 7. What is meant by the water line of a steam boiler and what relation must it bear to the positions of the supply and return mains for the proper working of a gravity job?

20 8. What is a false water line in a steam heating job and is it a satisfactory method of overcoming differences in levels?

5 9. What is the usual pressure on the boiler of a first class gravity system of heating?

10 10 What is meant when it is stated that a building is heated by (*a*) exhaust steam

(*b*) live "

10 11. In piping a building for heating by exhaust steam what precaution must be taken as to the position and size of the steam main?

5 12. What service is performed by a Nason steam trap?

5 13. What service is performed by an Albany steam trap?

5 14. What is meant by the one pipe system of piping?

5 15. What is the cause of noise, etc. in a steam plant and how may it be avoided?

5 16. In a two pipe system of steam heating in what direction should the main steam supply fall?

10 17. Should the safety valve on heating boiler have a lesser or greater opening than on a high pressure boiler?

5 18. What is the object of a check valve on the main return?

10 19. Which is the better method to carry the return mains under the floor or above? State seasons for your reply.

25 20. What should govern the amount of heating surface to be placed within any room to be warmed?

5 21. Is any moisture given off to the air of a house by a hot water or steam heating plant?

VENTILATION.

10 1. What is the usual method of detecting impure air?

10 2. Why does a column of air pass up or down a flue?

5 3. When should an out-let register be placed in a room heated by hot air?

10 4. Does impure air rise to the ceiling, drop to the floor or does it do either?

5 5. What is the highest speed at which air can be brought into a room without causing a draught?

15 6. Is one opening out of a room for ventilation purposes better than two or more openings or not?

5 7. What is meant by upward ventilation?

5 8. What is meant by downward ventilation?

10 9. Which is the more satisfactory and why?

20 10. What amount of floor area and cubic space should be allowed in a school room per pupil?

Sanitary Science.

FINAL.

Values.

25 1. State briefly the general sanitary principles which govern the present system of plumbing work.

25 2. State what are the conditions governing the proper drainage of a house where waste, subsoil and roof water must be disposed of.

25 3. Draw on the accompanying plan the different drains which you would put down to drain and carry off all waste products of a house including subsoil and rain water.

5 4. What is the weight of extra heavy soil pipe?

5 5. Why is it necessary that soil pipe should be heavy?

10 6. What provision would you make for running the waste water from a refrigerator?

5 7. What is meant by the water test as applied to plumbing pipes?

5 8. What is meant by the smoke test as applied to plumbing pipes and fixtures?

15 9. How would you dispose of the waste matter from the plumbing system of a country house.

15 10. Give a sketch of a cesspool suitable for the reception of the matter of a country house.

10 11. State the advantages and disadvantages of back venting traps in plumbing work.

10 12. State the advantages and disadvantages of a breathing pipe.

10 13. How should a urinal be set up in a semi-public place?

15 14. Describe the best method of setting up plumbing fixtures in a private house.

10 15. How should the waste pipes of a plumbing system be set up?

15 16. What measure would you take to prevent any danger to health arising through emanations from the ground beneath a house?

15 17. What are the causes of damp basements in clay soil and how would you provide against such dampness?

15 18. What is an earth closet and what are its advantages and disadvantages?

10 19. What is an anti-syphon trap and what are its advantages?

10 20. How may a trap become unsealed?

10 21. What constitutes a good trap?

The Elements of Building Construction.

SIRST AND FECOND INTERMEDIATE.

APRIL 8TH.

MR. E. BURKE, *Examiner.*

NOTE: *In 1st intermediate 110 marks will be the greatest number obtainable and 50 per cent. the minimum to pass. In the second intermediate 130 marks will be the greatest number obtainable and 50 per cent. the minimum to pass. The Questions enclosed in brackets are not required of the first intermediate students.*

Values.

10 1. Draw to scale of ½" to the foot a section of a rubble stone Cellar wall 18" thick, showing footing course in proper proportion. Show how wall is built in Section and Elevation and indicate description of work in writing upon the drawing.

10 2. Draw to 1" scale plans of two Successive Courses of a one and a half brick wall at the angle of a building showing Flemish bond on exterior and English on interior face.

15 3. Sketch in Elevation a random coursed wall of squared rubble having a rockfaced plinth, quoins with margin draft and weathered coping. Also sketch section showing bond.

25 4. Show Elevation of a window to ½ inch scale 3'0" wide 6'0" high in a one and a half brick wall with Segmental Arch—one half the arch to be "bonded" 1½ brick in height and the other to be "rowlock" same height. Indicate on the elevation in a series of four courses each, three different kinds of bond. [Show ¼ full size section of jamb, head and sill. Sashes to be hung with weights.]

10 5. Show a flat stone arch over a 4 ft. opening with the stones joggled. What is a cramp?

10 6. Sketch a Scarf Joint 3'0" in a 6" x 8" timber. [Showplan and elevation and fastenings of a beam spanning 22 ft., the largest timber available being 3" x 12", stuff 16 ft. long, beam to finish 9" thick.]

25 7. Show Section of a brick trimmer-arch with trimmed joints, flooring and deafening.

15 8. Draw Section to ¼" Scale of a King-bolt roof-truss, having a span of 30 ft. Indicate the names of the different members.

10 9. Sketch section of Gutter and Eaves, wood or metal, suitable for the Canadian climate.

10 10. Sketch section of flat roof, (felt or gravel), at parapet wall and method of flashing.

10 11. Show a section, to a scale of 2" to the foot, of jamb and sill of an external door in 1½ brick wall, the frame being 6x4, and the door 1¾ thick, pannelled on the outside and bead flush on the inside.

17 12. What is understood by the terms: beam filling, brick-nogging, damp-course, bats, corbelling, grouting, template, parging, deafening, strapping, plugging, housing, morticing, tenoning' bridging, key (in plastering), wiped joint.

Nature and Properties of Materials.

FINAL.

APRIL 8TH.

MR. E. BURKE, *Examiner.*

NOTE: *80 marks will be the maximum number of marks possible to be obtained and 60 per cent. the minimum to pass.*

Values.

12 1. Name the source and method of obtaining lines. Name two different kinds and the nature of each.

12. 1. In Building a wall in a damp situation what should be the composition of the mortar? and why?

10. 3. What are the uses of Concrete and what is its composition.

12 4. Name at least four different species of stone in general use in buildings and the distinguishing composition and qualities of each.

10 5. Name the distinguishing features of a good brick.

10 6. Name at least five kinds of roof coverings and the relative advantages and disadvantages of each.

12 7. What are the principal merits of cast and wrought iron? and in what way are they most effectively employed?

10 8. Describe the character of a good quality of timber for building purposes.

12 9. Name two kinds of glass and wherein are they different What is the composition of good Oil Paint and of Varnish.

Technical Terms.

FIRST INTERMEDIATE.

NOTE: *100 marks will be considered a full paper.*

Values.

50 1. Define: Abacus, Fillet, Acanthus, Verge-board, Boss Coping, Voussoir, Cavetto, Chamfer, Architrave, Base Coping, Aisle Crockets, Mullion, Extrados, Console, Patua, Groin, Dais, Clere-storey, Transept, Surbase, Beak-head, Astragal.

10 2. What is a Chamfer Stop? Sketch one.

15 3. What is a Rose Window? Sketch one.

20 4. Sketch, roughly, any Gothic Roof principal, and name the various timbers.

10 5. What do you understand by a Broach Spire?

25 6. Describe the main features of any Church you know, using the proper technical terms for all parts.

20 7. Sketch a Classic Conice, and give the proper names to each member.

SECOND INTERMEDIATE.

APRIL 8TH.

S. H. TOWNSEND, *Examiner.*

NOTE: *100 marks will be considered a full paper.*

Values.

15 1. What is a Corbel Table?

50 2. Define: Cyma-recta, Fillet, Surbase, Gargoyle, Torus, Transept, Abacus, Mullion, Apse, Console, Flamboyant Bowtill, Voussoirs, Crockets, Achlar Annulet, Triglyph, Extrados, Boss, Caryatides, Clere-storey, Dais, Cavetto, Architrave, Astragal.

15 3. What are Chamfer Stops? Sketch one in the Norman and one in the Early English style.

20 4. Sketch three examples of Norman Plain Mouldings and name the members.

25 5. Describe any Church you know, using the proper technical terms wherever possible.

25 6. Sketch roughly a Column and Entablature in any order. Name the order, and each of the members.

FINAL.

APRIL 8TH.

S. H. TOWNSEND, *Examiner.*

NOTE: *100 marks will be considered a full paper.*

Values.

10 1. What do you understand by "long and short work?" Sketch an example and say where and when it was used.

35 2. Define: Tympanum, Trefoil, Echinus Apse, Cusp, Label, Mitre, Bowtill, Flamboyant, Corona, Console, Donjon, Cyma-recta, Fillet, Surbase, Squint, Throating, Torus, Gargoyle, Transept, Squinch, Extrados, Abacus, Modillion, Caryatides Dais.

10 3. What is a Broach Spire? Sketch one.

20 4. Of what members do Norman Plain Mouldings consist? Sketch three examples of Norman enriched mouldings, and give the proper name to each.

10 5. What is an "Impost"? Sketch one.

10 6. What is a Rose-window?" Sketch one.

20 7. Sketch a column entablature in any of the Greek orders, and name the members.

10 8. What is a Corbel Table? Sketch one.

25 9. Describe the roof and main entrance door of any Church you know, using the proper technical terms and names for all mouldings, fixtures, etc.

ILLUSTRATIONS.

RESIDENCES ON DORCHESTER STREET, MONTREAL, FOR MESSRS. SHEARER AND BROWN.—WRIGHT & SON, ARCHITECTS.

The above houses are situated on the corner of Dorchester street and Atwater avenue, and the view is taken up on Atwater avenue, looking on the front on Dorchester street. They are built of Nova Scotia red sandstone furnished and built by Mr. J. H. Hutchison, contractor.

They are lined on the front with terra cotta blocks.

In the plumbing the very best materials have been used, and all is fitted up very complete. The buildings are wired for electric light.

The flat portion or hollow roof is covered with Sparhani cement and the mansard with best red slate, cut round. Firewall, covering, nosing, etc., are all cold rolled copper, as well as all the hip rolls and terminals.

The ground floors are finished in oak, the first floor in whitewood and the balance in pine. All the interior detail is made to correspond with the interiors tone work. The front is richly carved.

The contractors for the work were as follows: Masonry, J. H. Hutchinson; carpentering, J. Shearer; plastering, P. C. Wand; plumbing and electric wiring, Robt. Mitchell & Co.; roofing, Campbell & Co.

PHOTOGRAVURE PLATE—ST. ANDREW'S CHURCH, TORONTO. W. G. STORM, ARCHITECT, TORONTO.

HOUSE IN ROSEDALE.—E. B. JARVIS, ARCHITECT, TORONTO.

ALEXANDRIA SCHOOL FOR GIRLS, EAST TORONTO.—HENRY SIMPSON, ARCHITECT, TORONTO.

HOW TO ESTIMATE.

By W. H. HODSON.

Following is a portion of the balance of the specification and bill of quantities accompanying the drawings of Baptist church, Walmer Road, Toronto, published in the CANADIAN ARCHITECT AND BUILDER for May. The remaining portion will appear in our next issue:

CARPENTER AND JOINER WORK.

Provide and fix all necessary centerings and turning pieces, none to be removed until authorized by the architects. Provide cambered lintels 6 in. in depth by the thickness of wall where required. Framing lumber to be of good white pine free from large or loose knots, shakes or other imperfections and to hold the full sizes shown or specified when fixed in the building. The portion showing below plaster line must be carefully selected free from dark knots, stains and cracks. The joists and rafters may be of sound well seasoned hemlock. The joiners' work to be executed (unless otherwise specified) with good quality of clear and well seasoned white pine lumber suitable for carving. The woodwork of front of platform and baptistry, panelling and tracery at back of platform, gallery front and casing of gallery beam, vestibule screw and the doors and jambs in auditorium and front vestibule, and strings of stairs to be of well seasoned black ash, kiln dried, and of best quality. The turned pillars in gallery front to be of black birch. The carpenter to hoist and set the iron columns and girders which will be delivered at the building by founder, who will assist carpenter in putting columns together, supplying and fixing the necessary bolts and doing any drilling required. Board over stone sills and weathering as soon as set. Provide seasoned slips 2½ x ⅞ in., to be laid on walls under bearings of joists, and elsewhere as required for fixing trimmings and at every 2 ft. in height of dressing room and vestry outer walls to which to nail battens &c., and provide all necessary wood, bricks, &c. Batten outer walls of vestry and dressing rooms with 2 x 1¾ batten at 16 in. centers (walls of church and vestibules will be finished in brick). Ground floor joists to be 12 x 2 in. at an average of 16 in. centres resting on walls, and on 10 x 2 in. beams. Beams to rest on walls and on brick piers, joists of porch, rear vestibule, dressing room and vestry, 10 x 2 in. at 16 in. centers. Gallery beams to be composed of ten 12 - ⅞ dressed boards breaking joint and well nailed. Gallery joists to be 10 x 2 at 16 in. centres; outlooks of same 2 x 6 in. Form rising plates with 2 x 4 in. stuff as shown. The rear gallery beam is to be carried in four dressed and chamfered brackets as shown; brackets to rest in stone corbels, and to be bolted to walls with ¾ in. bolts built into brick and well anchored. Deck joists of vestry &c., to be 10 x 2 at 16 in. centres, made up with 2 in. stuff to form slope of ½ in. to the foot. Form curves for skylight with 2 in. stuff 10 in. above roof, and line in inside with narrow matched and jointed sheeting with bend at ceiling line and moulding at top. Trimmers at stairs, flues, windows, &c., to be 4 in. thick. Put a course of 2 x 2 in. bridging between each bearing. Joists of tower to be 12 x 2 at 16 in. centres. The run beams or plates of main roof resting on iron columns to be formed with five thicknesses of 2 x 10 in. stuff breaking joint, and in lengths to span two bays—to be well spiked with 6 in. wrot. iron spike at 3 ft. spaces with double ⅜ in. wrot. iron bolts at all joints. Walls of clere story to be formed with 10 x 2 in. studding at 16 in. centres, resting on 6 x 10 in. dressed and chamfered beams cutting in between iron columns. Plate above this beam receiving ends of aisle rafters to be 2 x 10 in. spiked to studding wherever practicable; the framing timbers may be made up to several thicknesses of stuff instead of being solid. In such cases joints must be properly broken and work thoroughly spiked and bolted. Principal rafters, collars, tie beams, queen posts and wall pieces to be of the sizes figured on detail sheet, dressed and stop chamfered or turned and moulded as shown. Purlines 6 x 8 in., checked into principals and stop chamfered. Ribs on ceilings forming panels to be 2 in. thick, rounded at angles, curved ribs to be made up of several thicknesses of stuff, breaking joint and well glued and nailed. Carpenters to supply and fix all the bolts, straps, iron-rods, nuts, washers, stirrups, &c., in connection with the framing of roof and as directed. Common rafters and collars 6 x 2 in. at 16 in. centres, collars to be well spiked to rafters. Rafters of pinnacles to be 4 x 2 secured to 4 x 4 in. mast, built into brickwork. Case the run beams &c., with ⅞ in. stuff, forming frieze having angle moulding as shown. Form moulded cornices in wood cutting in between principals. Put moulded fillets or cornices wherever necessary at junction of wood or plaster work with finished brick walls.

Roofs, sloping and flat, to be sheeted with ⅞ in. matched boarding well nailed to rafters in widths not exceeding 8 in. laid to break joint. Put proper 3 in. rolls to ridges. Eaves and gables to have ends of rafters dressed; dressed and beaded soffit, dressed facia and moulding against wall. Eaves of pinnacles and buttresses to be moulded as shown. The foul air trunk connecting galvanized iron vent tube in loft of church to tower to have 6 x 2 joists, 4 x 2 studding and rafters; walls and roof to be boarded for slating, soffit to be sheeted with ⅞ matched and V jointed stuff, and floor laid with ⅞ in. matched stuff; hinged batten door in east side fastened with good bolt. Provide a valve in the same of light stuff, hinged at top and worked with rope and pulleys from gallery stage of tower. Carry this duct with matched sheeting into belfry as shown, and form small door, hinged and bolted, in the same. Sheet walls of clerestory on outside with ⅞ matched stuff. Lay ground gallery floors with good quality of well seasoned ⅞ in. grooved and tongued boarding, blind nailed to joists

and properly cleaned off on completion, boards not to exceed 4 in. in width. Form steps at gallery passages. Partitions shown on plans by a yellow tint to have 4 × 3 in. heads and sills, common studs 4 × 2 at 16 in. centres; door posts 4 × 4 in.; braces 4 × 3 in. Truss partitions where necessary. Stairs in tower and N. E. staircase to have 1¼ in. close strings, beaded, with moulded capping and string mould, 1½ treads, rounded nosings, cavetts, and fillet, ⅞ in. risers, 7 × 6 in. turned red oak newels, 5 × 3 in. moulded red birch rail, and 1¾ in. turned birch balusters. Stairs in tower from gallery level to next stage to be generally similar, but with 5 in. newels and 4 × 3 in. rail. Enclose at head with ⅞ matched and jointed sheeting with panelled door hung with 4 in. butts and finished with good mortice lock and porcelain and plated furniture. Stairs to have all necessary carriages, brackettings, &c., &c., complete; sheet soffit of stairs with narrow and jointed stuff. Stairs to basement to have 1¼ treads, no risers, rounded nosings, 1¼ strings, rounded rails. Stairs to tower belfrey from upper floor to have 1¼ strings and treads, rounded rail and 4 in. newels. The windows of vestry and dressing rooms to have proper boxed frames with all necessary lines, weights &c., 1¾ in. moulded sashes fastened with Berlin bronze automatic fasteners and furnished with brass ring window lifts. All basement windows to be protected by wire guards of stoutest wire well secured to frames. Windows of church tower, vestibules, &c., 10 have solid moulded and rebated frames with stops to secure lead lights and beaded fillets outside and inside as shown, ventilators and gablles to have chamfered frames and ⅞ in. louvres. Put hinged batten doors on inside, fastened with bolts. The doors to basement area to be 1¼ in. thick bead and butt hung with 6 in. butts and furnished with two 8 in. barrel and two 8 in. square bolts to each leaf; provide strong hooks. Frame 4 × 6 chamfered and rebated 2 in. rounded oak sill. Door at back of west porch to be 1¼ panelled and chamfered, hung with 5 in. Berlin bronze butts, furnished with 5 in. good mortice lock, bronze knobs—4 × 6 chamfered and rebated frame, 2 in. oak sill. The entrance doors on east front to be of oak 2½ in. thick, panelled as shown, with rounded stiles and raised panels. Doors to be hung with 3 best 6 in. butts to each leaf, furnished with heavy square bolts to both leaves, and ecclesiastical escutcheons and drop handles of selected design. Provide and set also ornamental cast iron hinge plates according to detail; frames to be rebated and moulded with stiff bead and moulded tracenid fanlights with stop to secure glass. Provide heavy wrot. iron hooks to hold doors open. The swing doors immediately inside of the foregoing to have moulded frames finished above with crwon mould. Doors to be 1⅛ in. thick, panelled, moulded, veneered with black ash and prepared with stops for glazing; to be hung with Chicago double action spring hinges, nickel plated, and furnished with 12 in. polished copper finger plates, both sides. The other swing doors from vestibule to tower and staircase to be similar, also that from rear porch to vestibule, except that the latter will be of pine and will have japanned hinges and porcelain finger plates. The swing doors opening into gallery will be similar to those in front vestibule, but without glazing. The external doors of porch at rear of church to be ⅞ in. matched and beaded boarding 2½ in. framed and chamfered stiles and 1¼ inch back-rails, hung with three pairs of 5 in. butts to 4 in. rebated and chamfered frames, having 2 in. oak sills, and furnished with 8 in. spring and 10 in. barrel bolts and best heavy rebate mortice locks and 2 in. bronze knobs. Fasten back doors with strong brass hooks and eyes. Doors from church to rear vestibule to be 1¾ in. panelled and moulded, to be hung to moulded and rebated with two strong 5 in. Berlin bronze spring hinges to each leaf, and furnish with best 5 in. mortice locks, heavy copper bronze handles on one side, and copper iron finger plates on the other; standing leaf to have 12 in. bronze flush bolts, and strong hooks to hold both leaves open. Doors from church to vestry to be generally similar, but hinges not to be spring. Substitute also bronze knobs for handles and finger plates. Doors from front vestibule to church to be similar to those to rear vestibule in every respect, but prepared for glazing. Doors opening on to platform to be hung with three 4 in. Berlin bronze hinges to each and furnished with best 4 in. mortice locks, copper bronze knobs and furniture. All hardwood doors to be veneered. The doors in vestry and dressing rooms to be 1¼ in. panelled and chamfered, hung in proper rebated and beaded frames with 4 in. Berlin bronze butt hinges, and furnished with good 4 in. mortice locks, brass bolts and keys, porcelain and plated furniture. Doors in plastered partitions to have ⅞ in. simply moulded architraves 4½ in. wide with hand mould. Walls on ground floor leading to dressing rooms and vestry to be sheeted to height shown with ⅞ in. matched and V. jointed sheeting of the best quality, in widths not exceeding 4 in., blind nailed to grounds, and finished with moulded capping. Dressing rooms, lavatories and vesrry to have 8 in. moulded ⅞ base and 5 × ⅞ moulded, chair rail. Put fillet at junction of floor and base. Vestibule screen to be according to details, to have moulded posts or frames, boxed for weights. Dado of 2½ in. x ⅞ matched V jointed sheeting, double, forming pocket into which sashes may slide; sashes to be 2½ in., prepared with stops for lead glazing, hung with the very best sash cord over heavy brass pulleys and heavy weights, and bronze lifts as required. Form baptistry with proper studding and joisting, and sheet floor and sides with narrow matched stuff; curb to be moulded with moulded capping—proper detached solid steps in baptistry. Form turned and moulded columns at baptistry with moulded cornice, traceried panneling, &c., as shown. Pulpit platform to have 6 in by 2 in. joisting on proper supports—floor as church—front to be of panelling as shown, with rounded stiles and moulded capping and base. Put steps to platform as shown. Gallery front to be according to detail; turned balusters and traceried panels will be of black birch, also turned portion of newels at foot of stairs to platform. Provide and fix cut iron brackets on stays at about 5 ft. space well secured. The traceried panels will be at about 10 ft. centers. String mould rail balustrade of stairs from gallery to platform to be a continuation of gallery front as shown; form proper carriage and bearers of these stairs and prepare for plastering. Steps at side entrance to be 2 in. by 3 in. slatted and dressed 3 sides, 2 in. strings resting in cedar bearers, slat walk in front of same of similar stuff in cedar sleepers and having rounded curb. Partitions in lavatories to be of ⅞ matched V jointed sheeting 7 ft. high in 3 in. widths, finished with capping. Doors to be kept up 6 in. from floor, to be panelled and furnished with brass bolts and hung with 3½ butts. Plumber will supply seats of closets. Partitions forming dressing doors to be similar but extending to ceiling. Cope areas with 1¾ in. bevelled plank secured to brick work with ⅞ in. bolts 2 ft. long. Trim for registers and cut for steam fitters, pipes, &c., as required. Form side of coal bin with 2 in. plank on proper girth. Allow the sum of $100.00 for contingencies which will be deducted at final settlement if not required. Attend on other trades as required in the execution and for the perfect completion of the work.

IRON FOUNDER.

The iron columns to be delivered at the building, and the carpenter will hoist and set the same, assisted by founder, who will do any necessary fitting, drilling for bolts and supply all connections, fastchings and bolts. All bearings to be turned and columns to have top and bottom plates where required. Provide two basement columns under pulpit platform 4 in. diam. ½ inch metal. Provide six columns under gallery 4 in. diameter ⅝ metal, having moulded caps and shaft enriched with a diaper pattern of approved design. Provide and fix on ground floor eight columns, 10 in. diameter, ⅜ metal, having diaper pattern as above. Caps will be of plaster. The second stage of column will be ◯ shaped 10 in. diam. ¼ metal. Caps will be of plaster, as shown. The third stays of column will be 4 10 in. diam, 1 in. metal. All to have the necessary brackets, bolts, stays, &c., according to detail. Gallery front will be of wood. Provide and set across baptistry recess one 12 in, 1 be 10, 22 ft. 6 in. long, weighing 40 lbs. to the foot, and one 6 in. I beam 11 ft. long weighing 16 lbs. to the foot to carry back wall of organ recess. Provide and set two pairs of rolled iron girders across openings under gallery at tower and stair case, each girder to weigh 21½ lbs. to the foot and to have yokes and bolts with ornamental washers. Drill for screws securing wooden fillet on soffit to cover gap.

GALVANIZED IRON.

All the main eaves of nave and aisles to have 5 in., and eaves of tower, vestibule and staircase and vestry building square formed No. 28 galvanized iron, gutters properly secured to facias with wrot. iron brackets ⅝ × 1 in. and stiffened with 7/16 7/16 wrot. iron bars in best manner. Put fifteen 3 in. octagon galvanized iron down pipes properly connected at eaves with gutters and at foot with drains 1 ft. below surface, and having proper caps to pipes, secure to wall with ornamental wrot. iron hold fasts not more than 8 ft. apart. Put two stacks of similar pipes to tower eaves to waste on main roof and put 2 in. branches from the gutters in the other two sides connected to the 3 in. pipes. Flash at walls of church at deck of vestry building with galvanized iron 10 in. wide let into joints of brickwork cemented and turned down over felt. Cover wreathing of projection well on west elevation with No. 28 galvanized iron, lapped tacked and soldered. Provide and set glazed with rough plate two galvanized iron skylights having ventilators with valves opened by cords and pulleys. Provide and set on ventilating openings in ceiling of church ornamental register gratings and carry from the same to box near tower No. 28 galvanized iron ducts of sizes shown, carefully stayed and made secure and tight. Cover belfry floor of tower with No. 28 galvanized iron, lapped, tacked and soldered, and line with scupper and shoot to waste over church roof. Carry the iron 9 in. up on to wall and cement into joints of brickwork. Put galvanized iron shield in front of duct opening over roof of N. E. staire use held in place by wrot. iron brackets.

SLATER.

Line valleys with galvanized iron 15 in. wide. Cover saddle at back of tower with No. 28 galvanized iron carried up 2 ft. on to roof of church. Cover ridge rolls. Flash under sill pieces at junction of clear-storey walls, aisle roofs. Cover the sill pieces also and carry the iron well up behind in all tiles—say 5 in. Step and cloak flash at chimneys, tower, gables, &c. as required. Cover walls as shown and roofs of pinnacles, tower and stair case, with hard burned dark red tiles of best quality (Ontario or Toronto Pressed Brick Co's.) of patterns to be selected. Form hips at tower and pinnacle roof and provide and set terra cotta finials as shown bolted with iron rods to wood work of spire, &c. Cover the other sloping roofs with medium sized Canadian slates from the Rockland quarries laid on heavy felt. Put a double course at eaves. Slate the weatherings in west elevation, also the walls and edge of gangway to tower. Cover flat roof of vestry building with best felt pitch and gravel roofing, guaranteed for five years in writing. Repair and make good after other trades and leave all perfect and complete.

BILL OF QUANTITIES.

CARPENTER AND JOINER WORK.

	$	c.
6,600 ft. of pine timber (board measure) in beams, purlines, plates, etc.		
25,300 ft. of hemlock timber (board measure) in joists, rafters		
11½ squares (100 ft.) of 2"x1¼" battening, outer walls of dressing room and vestry		
12 squares (100 ft.) of 10 in. x 2 in. studding, clear story		
50 squares (100 ft.) of 2 in. ribbed work, in roof, ceilings, forming panels, curved at angles		
72¼ squares of ⅞ matched roof sheeting, 8 ins. wide		
9 squares of ⅞ matched sheeting to clear story		
1⅛ squares of ⅞ matched floor		
1½ squares of ⅞ matched and v jointed sheeting		
120 lineal ft. of platform fronts, best quality black ash, kiln dried		
72 lineal ft. of baptistry panel work, tracery and gallery front, kiln dried		
24 lineal ft. of casing gallery beam		
262 lineal ft. of run beam on iron columns, 5 thicknesses 10 in. x 2 in. and ⅞ freize casing, bolts spiked, etc.		
262 lineal ft. of dressed chamfered 6 x 10 beam		
160 lineal ft. of forming cornices mould at principals, and junction of wood work and plaster at brick wall		
232 lineal ft. of 3 in. rolls to r dges		
430 lineal ft. of dressed eaves and beaded soffit, etc.		
147 lineal ft. of pinnacle dressed eaves		
12 black ash doors and jambs, auditorium, vestibule, etc.		
5 pairs roof principals wrought and moulded, as per section		
10 pairs roof principals similar, wrought and moulded to aisles		
1 hinged door in tower floor bolted		
1 valve hinged and with ropes and pullies, to belfry, and with small door hinged and bolted		
173 stair steps finished, etc., as specified, different widths, strings black ash and open treads to basement		
4 black birch turned pillars, gallery front		
4 dressed and chamfered brackets to gallery beam, on stone corbels, ¾ iron bolts in brick wall, anchored		
11 rows of 2"x2" bridging		
Provide and fix centres, etc., throughout, provide cambered lintels, 6 in. wall thickness, hoisting and setting 16 iron columns, 6 beams and girders, to receive assistance from iron founder		
Boarding over stone sills and weathering, etc., as required		
8½ squares of ⅞ in. G and T gallery floors, 4 in. wide, stepped at passages		
34 squares of stud partition, trussed where necessary		
7½ squares of 4 in. x ⅞ in. v jointed wall sheeting mould, capped		
30 lineal ft. of vestibule screen mould, frame boxed for weights, etc., complete		
192 lineal ft. 8 in. mould base and chair rail		
78 lineal ft. ⅞ in. matched v jointed sheeting, double for pocket to slide sashes, complete		
28 lineal ft. dado, 2½ in. x ⅞ in. matched, v jointed, 7 ft. high, capped part up to ceiling, complete		
40 lineal ft. of area coping, 1¾ in. bevelled plank		
1 panel door head of tower stair complete, as specified		
2 1¾ in. doors to basement area, head and butt, hardware, etc., complete		
1 1¾ in. paneled door, west porch, hardware, etc., complete		
2 2¼ in. oak entrance panel, and faplight door, double hardware, etc., complete		
2 1⅜ in. swing entrance panel door veneered with black ash, hardware, etc., complete		
2 2¼ in. rear porch door, framed and filled with ⅞ in. matched and beaded boards, hardware, etc., complete		
6 1¾ in. panel doors, from church to rear vestibule, for glass, vestibule to church and vestry, finer plates, hardware, etc. complete		
2 platform doors, hardware, etc. complete		
4 1¾ panel doors in vestry and dressing room, complete		
4 doors to lavatories 6 in. up from floor, etc., complete		
7 basement doors and 1 large borrowed light, hardware, etc., complete		
4 sliding doors, per plans, hardware, etc., complete		
7 2¼ sashes, stops for lead glazing, sash, cord, pullies, weights, etc., complete		
6 2¼ sashes over same, south elevation		
4 windows (English) to vestry and dressing room complete		
7 windows, church towers and vestibules, stops for lead lights and heads, fillets inside and out, ventilator, etc., complete		
25 basement windows and wire guards complete		
36 clere story windows complete		
1 large brief window, north elevation, complete		
1 pulpit platform, panelling round stiles, mould cap and bases, steps, etc., complete		
1 2 in. plank coal bin		
Trimmers for registers, and cut for steam fitters pipes, etc., attend on other trades and leave work complete		
Straps, iron rods, nuts and washers, stirrups, bolts, spikes, etc., in the above work as specified		
Add $100. for contingencies, (if not required deducted at final)		

NOTE.—Beginning with bearing timbers, (undressed) the measure, thus: joist 30 ft. x 10 in. x 3 in. = equal to 6 ft. 3 in. cube to bring into board measure; multiply by 1 (for a foot square) gives the board measure 75 feet. Flooring, roof boarding, studding, furring, &c., measured length and breadth, thus: 25 ft. x 16 ft. gives = 400 ft., equal to 4 squares of 10 ft. x 10 ft. Lineal measure of running feet applies to cornices and dressed work generally, the sizes stated either in quantities or specification. Items in numbers, such as doors, windows, &c., as above.

IRON FOUNDER.

	$	c.
2 ½ in. metal columns under pulpit platform 4 in. diameter		
6 ⅝ in. metal columns under gallery moulds and ornaments 4 in. dia		
8 ¾ in. metal columns on ground floor, 10 in. diar. caps and plinths		
1 beam 22' 6" long, 40 lbs. to the foot		
1 beam 11' 6" long, 16 lbs. to the foot		
2 pairs rolled iron girders 21½ lbs. to the foot		
Yokes, bolts, ornamental washers, drill for screws, etc., as required		

GALVANIZED IRON WORK.

	$	c.
577 lineal ft. of 5 in. No. 28 G. iron gutters, branches, etc., complete		
380 lineal ft. of octagon G. iron down pipes, 3 in.		
150 lineal ft. of No. 28 G. iron ducts, stays, etc.		
2 squares (100 ft.) No. 28 G. iron covering, belfry floors, cemented, and shoot to over church roof		
2 galvanized iron skylights, ventilators opened by cords and pullies		
4 ornamental registers, gratings to ventilating ducts		
1 G. iron shields to duct opening and brackets complete		
Flashing to walls at duct, and projections lopped, nicked and soldered		

NOTE.—The measurements for this work as given above, lineal.

SLATER.

	$	c.
19¾ squares (100 ft.) dark red tile covering walls, roof of pinnele, etc., approved		
75 squares (100 ft.) Rockland slating on 1 ply tarred felt		
50 lineal ft. Rockland valleys, 15 in. wide		
140 lineal ft. flashing clere story covering sills, etc.,		
152 lineal ft. of step and cloak flashing, chimnies, tower, gables, etc., complete		
100 lineal ft. of slate weathering, west elevation		
1 saddle covered with G. iron at tower		
1 terra cotta finial bolted to wood work		
Repairing and making gooth after other trades		

NOTE.—Measured, and contents given in squares, before mentioned lineal measure, also, and the sizes as above.

HYDRAULIC CEMENTS NATURAL AND ARTIFICIAL, THEIR COMPARATIVE VALUES.

(Continued from May Number.)

To be sure, the Portland costs twice as much, but it tests twice as high; therefore it is to be expected to cost accordingly. We are apt to lose sight of the fact that both classes of cements sells for just about the same price at the mills, and that the increased cost of Portland is due to ocean freights, duties, dock charges and importers' profit, and even the most zealous advocate of Portland cement cannot claim that these charges can, in anyway, enbrace the intrinsic value of that cement. But higher price generally means better quality and backed by the testing machine, the engineer is perhaps justified in his opinions.

The testing machine is a good thing if put to its legitimate use. It is the abuse of it that we object to. It should occupy a subordinate place. If this were thoroughly understood, all would be well, but unfortunately the resquisites to a thorough understanding of a proper use of the machine requires more time and study than it does to learn to make and test a briquette. It consists in knowing soinething of the chemistry of a cement; in knowing what a table of analysis means; in having a knowledge of true combining proportions, and the effect of variations therefrom. Then the testing machines become a valuable auxiliary, for its readings will then have taken on a new meaning. The student will find that many of the rules and regulations governing tests, that have been built up within the past few years, are unsound and need revision.

The testing machine reveals many curious freaks, and taken on the principle that "Everything is for the best." it may yet reveal to us that a cement may test too high, that this modern demand for high-testing cement and the tremendous struggle on the part of the Portland cement manufacturers to supply it, striving by every conceivable means to beat the record, is all wrong.

This may sound strangely at first, but a study of the tables of long-time tests of Portland cements, as complied by such engineers as Clarke, of Boston, and MacClay, of New York, and others eminent in the profession, reveals the rather startling fact that briquettes of neat Portland do not test as high at 3 or 4 years as they do at 1 or 2 years old. Clarke says: "They become brittle with age and are apt to fly into pieces under comparatively light loads." If this is the result with neat cement at that age, what is to prevent the same results with sand mixtures at 15 to 20 years or so? I have seen walks that were made with Portland cement concrete remain in perfect condition for 8 years, and during the ninth year go all to pieces. An examination of the broken pieces shows the concrete to be exceedingly hard but brittle.

The ten years' tests of Portland cement made by Dr. Michaelis of Berlin, show that the maximum strength was reached at the end of two years, and this point held fairly well until the end of the seventh year, but from that time until the end of the tenth year there was a remarkable falling off in values. "We do not recollect ever having seen any table of long-time tests of Portland cement that did not exhibit similar results, and it is more than probable that it may yet be shown that our natural, slow-setting American cement may, in 10 or 12 years' tests, surpass any artificial cements. The excellent condition of some of our old work, done many years ago with American cements, would seem to indicate as much.

At all events, we have no proof that the Portland is superior in matter of durability, and we do not beleive that clay and lime can be suddenly thrown together, and kept there by any skill of man, that can in any manner compare with the staying qualities as found in first-class natural cements where the clay and lime have existed in the most intimate contact for countless ages.

During the past summer the engineer in charge of the Aberdeen harbor sea works, reported a serious failure in the Portland cement concrete work at that point; after only 15 years immersion it went to pieces, while the natural cement contrete, at the *same place* and *same age*, was in good condition. He states that every care had been taken in the Portland concrete used; the cement had withstood the *mechanical tests*, and the concrete had set hard. After a thorough examination by a Board of Engineers, assisted by Professor Brazier, of Aberdeen University, it was concluded that "Portland cement cannot resist the action of sea water." The Professor further states that "A chemical action had taken place between the sea water and the Portland cement in the concrete, causing an expansion and softening of the concrete." The harbor engineer also reported that "the Portland cement concrete entrance walls of the dock had expanded 2¾ inches in the height of the walls, and their surfaces had cracked and bulged, and the joints of the caisson Quoin-stones had opened up, causing considerable leakage."

Another case is that at the harbor of Dundee, reported upon during the past summer. In this instance the Portland cement concrete had softed in sea water and natural cement was used to protect it if possible from further distastes.

The investigations of Professor Tetmajer of the Federal Polytechnical School at Zurich, developed some interesting information. It has long been noticed in Germiany that Portland cement of certain kinds, when exposed for several years to the air, loses its consistency and crumbles. This danger had become so serious that the German Minister of Public Works issued a circular in 1885, restricting within narrow limits, the use of Portland cement in work exposed to the air.

Since that time Professor Tetmajer has devoted himself to investigating this matter, and, according to his statements, the cause of the disintegration of Portland cement exposed to air is to be found in a want of proper preparation of the materials, particularly in the lack of sufficient grinding together of the chalk and clay to ensure the complete silfication of the lime during the process of calcination.

But the best brands of Portland cement, which had withstood the action of water for several years, became soft on exposure to air. He says also, that "air especially attacks sharply (heavy) burnt cements, which imbibe a great deal of carbonic acid, and decay in water is caused by an excess of matters which undergo an increase in volume by oxidation and imbibing of water." The Professor found about 10 per cent. of the brands tested in this condition.

In the light of this exposition of the characteristics of both the English and German Portland cements in the countries where they are manufactured and where they have been the longest in use, it would seem that no other or better evidence is needed to prove that artificially-made cements, however high they may test, are not true cements, and the people of this country who of late years, are using Portland cements with such unlimited confidence in the superiority of those brands over our own natural cements, a confidence born of the testing machine and nurtured in the belief that tensile strain can be as unerringly applied to cements as to iron or steel, may yet awaken to a sad realization of the deceptive character of such tests, for it may well be predicted that in a very few years, we shall see evidences of disintegration and decay in many of the important works now being constructed of Portland cement in this country. When we compare these early indications of decay on the part of these new-born artificial cements with the splendid record made by natural cements that have successfully withstood the action of sea water for over a century—and the still more trying action of the air for centuries—reaching nearly if not quite as far back as civilization itself, we are inevitably led to the conclusion that man has not yet succeeded in compounding the materials essential to the production of a first-class cement, that can surpass, in durability and general excellence, that which nature has so bountifully bestowed upon us.

ERRATA.

Editor CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—I find that a printer's error occurs in the description of Mr. E. A. Well's house illustrated in your last number. It should read, "The half timber framing is constructed of 2 in. x 6 in. studs," instead of 2 in. x 2 in. studs as appearing in your publication. Kindly correct same and oblige.

Respectfully yours, J. FRANCIS BROWN.

The Adamant Mfg. Co., of Syracuse, N. Y., having recently purchased the property and business of the Northwestern Adamant Co., of Minneaplis, has been reorganized with a capital stock of $50,000 under the name "Adamant Mfg. Co. of America." The new company has branches in New York, Milwaukee, West Superior and Toronto. The latter branch will continue under the same management as heretofore.

CANADIAN ARCHITECT AND BUILDER.

VOL. V.—No. VII. TORONTO AND MONTREAL, CANADA, JUYL, 1892. { PRICE 20 CENTS. $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),

PUBLISHED ON THE THIRD SATURDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

14 King Street West, - TORONTO, CANADA.

64 TEMPLE BUILDING, MONTREAL.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMETS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

THE first step towards affording free technical instruction to the artisan classes was taken in Toronto at the beginning of the present year, when the City Council made a grant for the purpose. The results are said to be very satisfactory, and such as to warrant the continuance of the undertaking. The attendance has not been far short of two hundred, and it is gratifying to learn that a large proportion of the students have come from the ranks of workmen connected with the building trades.

IN a letter published in this number an architect asks for information concerning the varieties of Canadian building stones and the names of quarry owners, and expresses surprise that this information is not to be found in our advertising pages. It is obviously to the interest of every manufacturer and dealer in building appliances to keep his materials and his name and address before the notice of the principal consumers. The advertising pages of this journal are undoubtedly the best medium for that purpose.

THE Toronto Builders' Exchange continues to make satisfactory progress. The brick manufacturers have recently connected themselves with the organization, and now constitute one of the sections of the Association, the total membership of which has reached about one hundred and fifty. The new rooms which are being fitted up at the corner of King and Victoria streets for the use of the Exchange, are expected to be ready for occupation in less than a fortnight. Preparations are being made for an enjoyable house warming to mark the removal of the Exchange to its new home.

THE Dominion Parliament has appropriated $10,000 to the purpose of erecting a statue of the late Sir John A. Macdonald. It is said to be the intention to invite competitive designs from Canadian and European artists. A rare opportunity is thus afforded of displaying the worth of native talent. Care should be taken to make the most of it. The result of the efforts put forth by Canadian artists in this competition will have a distinct effect upon the future progress of art in this country. Much will also depend upon the wisdom which the government may display in the selection of competent and impartial persons to judge the designs.

THE *Building Register*, of Washington, makes the suggestion that in office buildings hereafter constructed, provision should be made for the storing of bicycles. It is pointed out that at present person's using these machines must leave them outside, where they obstruct travel or are exposed to thieves, or place them in corridors and halls, where they are equally out of place. The number of users of bicycles is very large, and they are such an indispensable means of locomotion in many branches of business that the number is rapidly increasing. If the increase is as great in proportion in the future as it has been in the past the law-makers will be obliged to take in hand the matter of keeping them off the street.

A DEPUTATION waited on the Minister of Customs and Public Works a few days ago to ask for an increased duty on Portland cement; also that the standard of this material be made as low as is compatible with public safety and that preference be given on all public works to cement manufactured in Canada. Considering that hardly any two persons conducting a test will attain to the same results with a given brand of cement, it seems to be a matter of little importance whether the standard

be a high or low one. Theoretically, however, it would seem to be proper that the government standard should be fixed reasonably high.

THE important position of City Engineer, Toronto, which has been allowed to remain vacant for a year, has finally been filled by the appointment of Mr. E. H. Keating. Mr. Keating was formerly City Engineer of Halifax, and occupies at present a similar position at Duluth, Minn. His reputation would indicate his fitness for his new position. The successful administration of this most important department of the city service will certainly afford scope for ability of the highest order. The amount connected with the appointment as salary was placed at $4,000, but Mr. Keating asks $5,000. The sum is not too great for a first-class man, but the mayor's right to assure Mr. Keating that the extra $1,000 a year would be given him, without having laid the matter before the Council, is open to question.

THE district immediately north of Bloor street has within the last four or five years come to be regarded as one of the most desirable for residence purposes in the city of Toronto. This is due in a measure to its favorable location in proximity to the Queen's Park, the colleges and university, as well as the excellent street car accommodation, but more particularly to the fact that building restrictions are imposed governing the sale of lands, making it impossible for a cheap class of houses to be erected. In view of the precautions thus taken it is very disappointing to find that the result sought to be attained has to a large extent been defeated by the unsatisfactory character, in point of design, of the buildings erected. Unfortunately, much of the land in this locality has fallen into the hands of the speculative builder, who, while obliged to comply with the restrictions as to cost, is under no compulsion to have his designing done by other than a third-class architect. As a result we see a vast amount of good material which might have been made to assume forms of beauty delighting the eye and refining to the taste of the onlooker, wrought into forms of ugliness. Out of the hundreds of houses erected in this beautiful locality within the last five years, the number that can be said to be satisfactory in design might easily be counted on one's fingers.

THE introduction of the trolley electric system for the propulsion of street cars in Toronto was strongly objected to because it would result in adding to the number of overhead wires. When the fact was demonstrated that the trolley was the only successful system which could be adopted, the objectors had no alternative other than to philosophically try to make the best of the situation. There is a strong probability that with the electric street railway will come an improvement in the present arrangement of overhead wires, by which to a large extent their unsightliness and danger will be removed. It is understood that the street railway, electric light and telegraph companies have expressed their willingness to occupy jointly two lines of poles planted on either side of all streets on which cars will run. It is proposed to erect iron poles of sufficient height and strength to carry all the necessary wires. The carrying out of this proposal would allow of the removal of thousands of the large poles carrying electric light and telegraph wires now disfiguring the streets. The advantages would be about equal to those of the underground system, and without the added cost to consumers of electric light which would be certain to follow the construction and maintenance of the conduit system. We hope to see the idea successfully carried out.

WE publish elsewhere a series of "suggestions" issued by the Council of the Royal Institute of British Architects, for the conduct of competitions. The proposal to have the expert appointed to judge the designs advise as to the limit of cost, is designed to place all competitors on an equal footing. It has been the practice in Great Britain to charge competitors ten dollars or so for a copy of the instructions, which sum was returned only in the case of those who furnished a *bona fide* design. As it sometimes happens that a perusal of the instructions is sufficient to cause the architect to decide to have nothing to do with the competition, and as he is not in a position without the instructions to decide whether or not the competition is one which he might desire to enter, the Institute suggests that architects should be entitled to be refunded the sum thus paid, in cases in which they do not desire to compete and in which they return the instructions within the period of thirty days. We are not aware that in Canada competitors have ever been asked to pay for the information necessary to enable them to decide whether or not they should comply with the invitation to compete. It is manifestly unfair that they should. The *Building News*, in discussing the value of these suggestions, admits that they embody many needed reforms, but says: "The main difficulty remains, the difficulty of finding in each case a suitable professional assessor. This has always been in principle, the weak point of the system. A happy accident has so far kept it from being very obviously such, but in course of time its weakness can hardly fail to become conspicuous. It is this difficulty, more than any other, which needs for the future the earnest attention of architects and their representatives." The appointment of three assessors, instead of one, should it be possible to obtain them, would no doubt tend to insure an impartial and satisfactory decision.

IT is said to be the practice of architects in Montreal to include the electric wiring of buildings in the plumber's specification. To entrust this work to the plumber, who, probably in nine cases out of ten has never devoted an hour to the study of electricity, seems like deliberately preparing the way for future difficulty. In this connection we quote as follows from a paper on "Safe Wiring" read by Mr. A. B. Smith, Inspector for the Underwriters' Association, at the recent convention of the Canadian Electrical Association: "While in a few instances much trouble and annoyance is caused by unskilled electric men, who have an idea they possess more knowledge than can be carried by one single brain, still there is a source of trouble to electric light people and the underwriters which is most serious. What I refer to is, the ignorant and clumsy interference with good wiring by plumbers, steam and gas fitters and other pipe men, and our friend the ubiquitous bell hanger. These individuals, with supreme contempt of others' rights, or through ignorance, not realizing the danger of their practices, are constantly making mischief. Nine cases out of ten, where trouble is located in an otherwise perfect piece of work, these pirates are to blame. It is a common occurrence to find gas or water pipes resting upon electric wires, these pipes or other iron work, having been placed in position after the electrical work was completed. Furthermore, there is a certain class of men, especially gas fitters, who really have an idea that they do know something about electricity, and who believe that because wires are sometimes run in pipes, that it is their special vocation to do it. It is true in this as in other matters, that 'A little knowledge is a dangerous thing.' Unfortunately the public have no protection against these half-baked electricians, and it is against this class of work that the insurance companies have to fight their greatest battles. Serious loss has only been averted by constant and skillful supervision, and were it not so, the loss from this source would be vastly greater."

THE wisdom of the large expenditures of the Dominion Government in the construction of canals, as well as in the deepening of those canals sufficiently to admit of the passage of heavily laden vessels from the great inland lakes to the seaboard, is now becoming apparent. As a result of the advantages in the amount of cargo and saving in cost of transhipment offered by the Canadian route over the Erie canal, the exports of grain and flour of the city of New York are steadily decreasing, while those of Montreal are to a proportionate extent increasing. In consequence, the Americans are becoming alarmed, and in the House of Representatives it has been proposed to make an appropriation to cover the cost of a survey to determine the most desirable and practical route for a deep water canal wholly within the territory of the United States, from the great lakes to deep water in the Hudson river. In view of these circumstances, and of the fact that the volume of water transportation as compared with transportation by rail is shown by trade statistics to be on the increase, we are pleased to see the revival of the project to connect Lake Ontario with the Georgian Bay by means of a ship-railway. If this connection were made, either by ship-railway or canal, it would be the means of shortening the route from the grain-producing districts of the northwest to the seaboard by some four hundred miles, and would give Canada an advantage which it would be impossible for her to be deprived of. It would be the means of building up the interests of Toronto and Montreal, of developing our shipping and of promoting trade between this country and Great Britain. The cost of a ship-railway is placed at $12,000,000 to $15,000,000. The cost of the proposed American canal is estimated at $110,000,000. If, as is supposed, the saving in cost of transportation in deep draught ships from the lakes to the ocean, would in a single year amount to sufficient to pay this latter sum, there would not appear to be much risk involved in the Canadian enterprise at so much less cost, and in view of its greater advantages. The benefits to be derived from carrying out the undertaking, will depend to some extent upon its early commencement and speedy completion, in order that the volume of trade, which, as stated, has already begun to flow in this direction, may be encouraged, instead of being allowed to be diverted into other channels.

SCIENTIFIC NOTES.

THE MONIER SYSTEM OF BUILDING CONSTRUCTION.

BY LEWIS ANGELL.

At the meeting of the Science Standing Committee, 4th inst., I called attention to the Monier system of building construction which I have recently had the opportunity of inspecting in actual operation in Berlin. The system consists of a combination of cement or fine concrete with a net-work of wrought-iron wire or small bare forming a core. The system is applicable to a great variety of forms—viz., floors, ceilings, roofs, domes, walls, bridges, retaining walls, waterpipes, circular or oviform sewers, &c., and even the fortifications. Its recommendations are great strength, and economy in materials, space, and time. It is especially fire and damp-proof, and, to a large extent, independent of skilled labor.

The accompanying sketches will generally illustrate the system, which, as above stated, can be applied to various forms of construction.

Fig. 1 is an illustration of a fire-proof floor or arch about 10 feet span and 1¾ inch thickes. Upon an ordinary centre of planks a layer of cement and sand, in the proportions of 1 to 3, is laid one half the intended thickness of the arch. Upon this

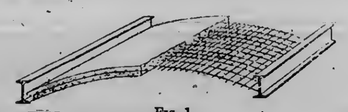

FIG. 1.

are laid longitudinally and transversely wrought-iron wires about ¼ inch diameter, so as to form a net-work with about 3-inch interspaces or mesh, the intersections being secured with fine wire. The net-work is then covered with another equal layer of cement, completing the thickness of the arch, the wrought wire net-work being thus embedded in the cement as a core. The spandrils are filled in with concrete in the proportion of 1 to 8. The thickness of the wire and the cement arch varies with the span and weight to be carried. The Hungarian Government tested a Monier arch, 2 inches thick, of 8 feet span, and 6 inches rise, by a distributed load of 31 tons with safety. Another arch 4 inches thick of 30 feet span carried a distributed load of 42 tons. A bridge has been constructed over the canal at Bremen with a span of 125 feet and 7 feet rise, having a thickness of only 7½ inches on the crown.

It has been proved by tests and expreience that the expansion and contraction of the cement and iron are equal, that cement and iron possess great affinities and become a solid mass, and

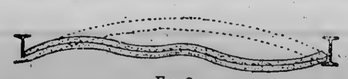

FIG. 2.

that the iron is not oxidized or otherwise affected independently of the cement. This form of construction give a maximum of strength with a minimum of material. It has also been proved by tests of the Hungarian Government that arches constructed on the Monier system will bear five times more weight than a corresponding best concrete arch, and that Monier slabs or landings will bear twelve times more weight than corresponding slabs of concrete. Another valuable quality of the Monier construction is that it will not suddenly break, crash, or collapse as in ordinary construction, but it gradually buckles or sags, retaining the weight above (fig. 2). The chief of the Berlin Fire Brigade has issued an official order that firemen are to enter buildings constructed on the Monier system, as there is no risk of floors and ceilings cracking and falling by reason of either heat or water.

The system has made great way in Germany, Austria, Hungary, and other parts of the continent during the last three years in connection with public buildings, palaces, warehouses, bridges, watefworks, tunnels, drainage, &c.

The foregoing is only a general description of the wonderful results on the continent of this new system invented by Mr. Monier and elaborated by Mr. Wayss, the eminent engineer-architect of Berlin; and capable of such wide application. Its conception in a modified form is not altogether new. There have been proposals to introduce a wire-wove core in various forms, but there has not hitherto been any serious application of the principle to actual construction, nor does there yet appear to be any instance of its adoption in this country. Its first intended application is to be in the deck of the new pier about to be constructed at Brighton, in the form of horizontal slabs or paving, whereby a considerable amount of time and the space it would occupy will be saved. The system is well worthy of the serious consideration of British engineers and architects.

ILLUSTRATIONS.

PHOTOGRAVURE PLATE—PROPOSED NEW UNION STATION, TORONTO.—STRICKLAND & SYMONS, ARCHITECTS.

The main building facing on Front street will be built of red Credit Valley stone for the two lower stories, and pressed brick with red Credit Valley stone dressing for the stories above, the roof being covered with red tile. The main entrance will be built of cut stone, floored in tile and leading into the main hall or rotunda, 40 x 50 ft., finished in oak, with tiled floors, the ceiling being panelled and enriched and the walls arcaded with stone and marble columns. The entrance to the company's offices will be by the tower entrance, which will contain an iron staircase and passenger elevators. Passing through the rotunda where tickets are purchased and baggage checked, the arcade corridor 20 ft. wide leads to the main waiting room. On either side of the corridor the store will be handsomely fitted up in most modern style.

The general waiting room 75 x 80 ft. will be finished in pressed brick and cut stone, with heavy enriched and panelled oak ceiling, with colored glass dome sky-light, light being also obtained from clerestory windows on three sides. The floors of this room and other waiting rooms will be laid with mosaic flooring. The ladies' and gentlemen's waiting rooms will be fitted up in hardwood, with decorated plaster ceilings, and the lavatories in connection with both of these rooms will be fitted up in the very latest and most complete style. Conveniently situated off the main waiting room will be the telegraph and parcel offices and news stand, with their respective fittings specially designed for their various uses. The outer or bridge waiting room will be finished in ash or other hardwood, with plate glass windows and doors. Two passenger elevators each capable of holding 40 persons will connect this room with track level, and also a handsome staircase ten feet wide finished in hardwood.

The new south train shed will be entirely of iron and glass and conform to the latest improvement in train shed construction.

The lighting throughout, and all power for elevators and other machinery, will be by electricity supplied from plant in the basement of main building. Heating throughout will be by steam.

The expenditure for the entire building will approximate $500,000.

POWER HOUSE, HAMILTON ELECTRIC STREET RAILWAY COMPANY, HAMILTON—JAMES BALFOUR, ARCHITECT, HAMILTON.

"CANADIAN ARCHITECT AND BUILDER" COMPETITION FOR A TOWN COTTAGE—DESIGN SUBMITTED BY "VERISOPHT."

DESIGNING A HOUSE.

A writer in the *Magazine of Art* says: In the actual process of designing a house, the plan cannot be separated from the elevation and sections; the architect's mind keeps playing backward and forward from the one to the other, so that the building grows up in his mind as an organic whole. To put it in other terms, while he is at work on the plan he is constantly considering the effect of his plan on his elevation, and vice versa. The results of the work are duly displayed in plan, elevation and erection; and this, no doubt, leads to the false impression in the lay mind that the plan and elevation can be considered apart, and are not in necessary relation to each other. As the plan is embodied in the elevation and sections that is, in the actual walls of the building the two must be considered together in practice. With this provision, there are one or two matters which more particularly concern the plan. The main points to aim at are simplicity and compactness of arrangement and plenty of light. A long, crooked passage with constant changes of level, may be very romantic and admirably adapted to the habits of the "Decameron," but with the hurry of the modern household and the unadroitness of the domestic servant, it means cold dishes and disaster with crockery, and general discomforts and ill-temper. There has been a tendency lately to overdo the queer corner and the curious passages. I have a book before me, sent out by a well-known firm of furnishers, in which there are half a dozen or more designs for inglenooks and bays and recesses which do not result from any necessity of the plan, but are placed at random with no particular object but that of looking queer. The real old ingle is quite delightful, with its great cambered oak-beam across the opening, 14 feet wide or more, and its red-brick floors and the old muzzle loader over the chimney piece, and the little lead-glazed lattice with its dimity curtain; but how far away from this is the affectation of a modern ingle-nook, with its aggressive grate and mechanically stamped paper frieze and fillings of "art-fabrics." If you are going to have an inglenook, at least keep it plain and solid and comfortable, and have a hearth before which you can stretch your legs, and a fire place big enough to burn a reasonable, good oak log. So, too, with the passages: let them be wide enough for two people to pass, and light enough to prevent their falling into each other's arms. In country houses the position of the sitting room is usually determined by the aspect, and in a house of any pretension there is sure to be a good-sized hall and an ample stair case; but the hall is worth a sacrifice, even in smaller houses. The first impression you form of a house is very often the last, and your first impression is formed in the hall.

It is not in the least necessary that it should be two stories high. Some of the most charming little halls in seventeenth century and modern work are long, low rooms, sweet and homely to live in, places never haunted by the ennui of magnificent dreariness. For moderate house the one-story is rather an advantage because it practically gives another sitting room, and in quite small country houses, such as those that are used, say, for summer holidays, why not return to the plan of the yeoman's house of the sixteenth century and earlier, when one great hall was the general living room, and at one end were the kitchen and offices and the servants' rooms, and at the other the solar and the rooms of the master and his family? A house costing less than $5000 could have room enough for a billiard table or a dance, such as would be quite impossible in the stuffy, respectable house up the village built by the squire when he came of age. The reason for such a room would not be mere picturesqueness, but its manifold uses, its essential reasonableness, and the same reasonableness would not be afraid of the plainest work; of showing the rafters or the ceiling joists, or of lining the back of the fire place with honest red brick.

TO PUT ON HARDWARE.

By Owen B. Maginnis.

All working parts of joinery have moveable fixtures to secure them to those parts which are fastened or permanent. So fixings, or as they are better known "hardware," are manufactured for this purpose. By "hardware" is meant the iron and brass hinges, locks, etc., which are placed on doors, windows, and such like, and the purpose of what follows is to show the carpenter how to put it on properly.

Should the doors be of various heights, take two standard distances, say nine from the bottom and six from the top, or if desired, place the hinge just below the bottom edge of the top rail, and above the top edge of the bottom rail. Mark the two ends of the hinge with the point of a penknife, then set a guage to suit the width which will be necessary to let the hinge into the door-edge, which width will be regulated by the width of the hinge itself and the thickness of the door, in order that the screws which are to hold the hinge may be turned solidly into the wood and still leave a ⅛ or ¼ margin. A second guage will require to be set to the thickness of the hinge, allowing a little margin, that when it is let into the beveled edge of the door, it will come about square to the face. It must not, however, be so much sunk as to cause it to hingebound when hung. When the sinkage is made in the edge, the hinge can be inserted, and if it be a loose jointed or loose pin hinge, one piece may be set in and the pin side kept up. Should the hinge be a cast iron or japanned one, the end of the handle of the hammer might be used to knock it into place, but if it be of lacquered, bronzed or buffed brass finish, a neat clean block of soft white pine must be brought into use to avoid injuring the polished surface.

The hinge should not be make to fit too tight, as it may be found necessary to take it out again, and if it fit too closely there is a liability of sprawling the corners in doing so.

Brass screws must always be driven with a firm, square edged screw driver and care must be taken, that the point does not jump out of the slotted head of the screw, so as to mark and scratch the head.

In hardwood finish, brass screws should be well bored for with a German bit, and they should be slightly greased with a little soap or beeswax before being placed in the hole.

It is scarcely wise to hammer brass very much as brass is a soft metal, and the screw is liable to bend under the stroke of the hammer.

When the hinges are screwed on the door edge, place the door in the frame in the rebate, and wedging it up from the bottom so that the top edge will be an easy point, mark the positions of the hinge sinkages, (with a pocket knife) and cut out the wood as before, avoiding sinking it too deep, lest it should be found necessary to block out the hinge again with shaving or paper. It is better to pare out a little than do this, but care must be taken that it is not what carpenters call "hinge bound" which means that the hinges are sunk in too much, and the hinged joint is too close.

The only way to become an expert door hanger is by practice, and care should be exercised while learning in order to put the hinges on without injuring them and make the door work properly.

Single and double action hinges are much more difficult to put on than ordinary single action butts, still the makers give the carpenters great assistance by sending printed directions with sketches in each box showing the lock in position and in parts. This enables him to comprehend the way they should be set, and the directions and sketches ought to be thoroughly studied and understood before making a mark or using a tool. On no account should metal hinges be struck with a hammer as they are liable to fracture. Those of brass will stand a blow, but usually show the effect in bruise or dent.

Ordinary brass-faced mortise locks need nice fitting and require to be set in flush with the door's edge, and not project of the edge is bevelled. Brass door knobs and escutcheons ought, in all cases, to be covered with lawn, to prevent rough, sandy hands from scoring their polished surface. Tie the keys to the knobs, or, if this be risky, put a marked and numbered tag on each, in order that its lock may be readily found.

Patent door springs have printed directions, which must be adhered to to insure satisfactory working. Yale and other special locks need special cutting, and, therefore, a good machanic to put them on right; but the sketch in the box is a wonderful aid to novices. These locks ought never to be taken apart, on account of their intricacy. An error of this kind once cost the writer much expense and delay and a good wetting bringing it to the manufacturer's depot for readjustment.

In regard to sash locks there is little to be said, except that they require to be put on so as to really lock the window namely, bind it close together at the meeting rails, besides preventing the sash from being moved. Fasten on escutcheons perfectly plumb and drawer-pulls level, and the slots of the screws in a line with the work. For instance, in escutcheons, finger-plates, hinges and lock-faces all the slots should be kept plumb, and no drawer-pulls, door-pulls, or any brass, iron or silver work, kept level or horizontal. English ship-joiners never put their screws in any other way but this.

The hardware of sliding-doors run on a track on the floor consists of the sheaves or rollers, the track on which they run, the lock and fittings and the iron door-stop above.

In fitting in the sheaves, the main thing is to get them in the centre of the edge, to bring the two doors fair and to have them project equally. The doors ought, of course, to be fitted till the joint comes, and when the inside wood stop is mortised in and cut the two can be set on the track which, by the way, comes in two lengths and the sheaves regulated till the doors close tightly. Enough should be allowed from the floor for carpet

saddle. The stop is let flush into the door-head and the lock put on in the usual way. No hardwood sliding-doors should ever be made without friction-strips, to save the arrises and faces of the door's surface.

Sliding doors hung from above with sliding door hanger demand an entirely different treatment. The track being of wood and screwed on the partitions necessitates their being put on before the second partition forming the door pocket is put up. It is best to line pockets, for these doors, with matched ceiling to keep the door from being scratched. Concerning the fitting and adjustment of the hangers I would say there are many very excellent makes on the market and each has its own special features and special directions which are sufficiently clear and explanatory for any one of ordinary intelligence to work from.

Fanlight levers, bolts, etc., are comparatively simple in their application and demand little or no direction, but the great thing to watch in putting on all hardware is to make it fit neatly, so that it may look well. All marking, therefore, should be exact to insure the piece fitting in its place and working freely, without sticking.

HOW TO ESTIMATE.

By W. H. Hodson.

Following is the balance of specification and bill of quantities accompanying the drawings of Baptist Church, Walmer Road, Toronto, published in the Canadian Architect and Builder for May:

PLUMBER AND GAS FITTER.

State reduction if gas piping be entirely omitted. Lay on from meter in basement best 1½ in. tested iron piping to ceiling of auditorium and carry from thence to points marked on plans, commencing with 1¼ and diminishing to ½ in. as required. Provide for three separate supplies, one to basement, porch and vestry building, one to the rest of ground floor, and one to the gallery, and place taps in places convenient of access in rear passage; all to be of best tested iron piping laid complete and made ready for fixtures with all necessary bends, junctions, &c., complete, and to be satisfactorily tested on completion. All drop lights to be taken out of side of supplies and in no case from the bottom thoroughly secure to joists or timbers. Lay on water from line of street with ¾ in. lead pipe of 8 lbs. lead to line of fixtures, and from thence ½ in. 6 lbs. to sink, baptistry, W. C's. and basins. Provide brass stop and waste cock immediately inside wall, and pipes to be graded to this point. Provide and set a double tube street washer hydrant where marked. Fit up in basement a cast iron sink 18 ft. long with 1½ in. waste pipe of lead, Dubois trap and trap screw, brass fuller cock. The two water closets to be Malcolm's No. 1 toilet, fitted up with cabinet work and double hinged hardware seats and having all necessary cranks, valves, &c., complete. There will be a 4 in. cast iron extra heavy soil pipe carried from W. C's. to drain. Extend the soil pipes a single pipe up to and 3 ft. above roof with proper open tops to the same. Soil pipe to be coated on both sides with coal tar applied hot, and joints to be carefully caulked with oakum and lead. Provide two brass cleaning screws where directed. Basins to be 12 in. diameter with 1¼ in. counter sunk marble tops and backs 9 in. high, 1½ in. lead waste, Dubois trap, plated plug and chain and plated self closing Hyde cocks. Line baptistry, which will be open, with 14 oz. tinned and planished copper in best manner and provide 2 in. heavy lead waste and overflow properly trapped and carried into drain—plated rose plug and chain. Move and connect present double jacket heater now in school building with 1 in. heavy lead circulating pipes to and from baptistry. Provide brass cock for emptying boiler with waste to baptistry waste. Provide galvanized iron smoke pipe and damper connected into chimney. Put 3 in. lead ventilators to traps of W. C's carried into soil pipe above fixtures and receiving 2 in. and 1¼ in. branches from traps of the other fixtures. All piping and materials to be of weights and description conforming to city by-laws.

PLASTERER.

All brick walls will be finished to show bricks, except in vestry and dressing room building. Plasterers will be required to exercise the most extreme care in order to preserve the pressed brick work from damage in any form. Supply the necessary cotton sheeting to prevent them being splashed with mortar. The inner face of outer brick walls of vestry building to be well parged, making tight and close at frames, etc. Lath with the best sawn pine laths the whole of the ceilings, partitions, soffits of gallery, battened walls in vestry building and other places, prepared for lathing; laths to be not more than 1 in. wide for ceilings and 1½ in. for walls, 5-16 in. apart, well nailed, ends butted, and joints broken every 12th lath. The partitions and ceilings and soffits of gallery and other places prepared for lathing, to be plastered in best three coat work, sand finish. All the corners will be of wood. Walls to be rendered behind all skirtings and sheetings. The mouldings of capitals of the 16 large columns (ground floor and gallery) to be in plaster freely executed. The folited capitals of the 8 columns in gallery to be in plaster modelled in most artistic manner by modeller to be chosen by the architects. The whole of the work to be of the best quality of materials and workmanship, the mortar to be prepared with clean sharp sand, lime and hair in proper proportions, and the work to be left free from cracks, stains, blisters, or other blemishes, and sound and perfect on completion after making good after other trades. Plasterer to leave all dressed woodwork clean and ready for painter. Remove all rubbish and broom clean floors throughout on completion.

PAINTER AND GLAZIER.

A separate tender is required for the lead glazing. Windows of basement to be glazed with —— sheet glass; windows of vestry and dressing rooms to be glazed with 16 oz. glass, the lower panes to be ground. Glass to be well puttied and back puttied, sashes to be primed before glazing. The iron columns to be painted three coats and picked out in bronze. Iron work of principals to be painted three coats of blue and bolt heads gilt. The whole of the external woodwork usually painted, including window and door frames, eaves, &c., to be painted in three coats of best white lead and linseed oil paint of approved tints. Eaves, gutters and down pipes to be painted two coats. The whole of the internal wood work, unless otherwise described, including doors, casings, roof timbers, skirtings, sheetings, &c., &c., to be cleaned, stained to such tints as may be directed and twice varnished with best copal varnish. The risers of gallery plates to receive one coat of stain in oil. Inside frames of windows to be painted three coats. The pulpit front, tracery over baptistry, doors of church and vestibules, vestibule screen, the strings, rails and balusters of staircase, and the gallery front will be of hardwood, to receive a thorough coat of oil, to be well filled with approved fillers, to receive two coats hard oil and rubbed down with pumice stone and sweet oil. Painter to clean sash windows and scrub floors before and after painting and leave glass perfect on completion. The ceilings of church and vestibule, tower and staircase, the walls in church when plastering, and the walls of ceilings of vestry to be calcimined in two coats of tints to be chosen.

LEAD GLAZING.

All the windows except basement and windows of vestry and dressing rooms (which are in painter's specification) will be glazed with leaded glass, also traceried heads of entrance doors and six sets of swing doors; all to be set in strong church lead, securely soldered and cemented and secured with strong copper wire to ½ round iron bars, properly japanned. Lead work to be bedded in frames in thin putty and stops to be closely nailed up to lead. Provide and fix as shown in elevations carefully fitted steel frame ventilators. The windows in loft to be glazed with clear glass in simple quarries. The windows of porch and rear vestibule and third stage of tower to be glazed with rolled cathedral glass of approved tints and in small quarries. The other leaded windows, traceried fanlights and vestibule doors and screen, to be glazed with muffled cathedral glass of delicate tints in varying geometrical forms with roundels and other features to be chosen by the architect. The six sets of swing doors will be glazed with clear glass set in lead made to geometrical forms with occasional roundels.

BILL OF QUANTITIES.

PLUMBER AND GASFITTER.

176 lineal ft. of ⅝ in. lead water pipe, 8 lbs. to the yard
400 lineal ft. of ½ in. lead water pipe, 6 lbs. to the yard
35 lineal ft. of 1½ in. lead waste pipe
18 lineal ft. of 2 in. heavy lead waste pipe trapped
230 lineal ft. of 1¼ in. iron gas piping
300 lineal ft. of 1¼ in. iron gas piping
556 lineal ft. of ½ in. iron gas piping
140 lineal ft. of 4 in. soil pipe (heavy) open traps, caulked with oakum and lead, coated with coal tar
1 brass stop and waste cock
1 double tube street washer hydrant
1 cast iron sink 18 ft. long
1 Dubois trap and screw
1 brass fuller cock
2 Malcolm's No. 1 toilet water closets hinged, hardware seat, cranks, valves, etc., complete
2 brass cleaning screws to soil pipe
2 12 in. dia. basins, 1¼ in. counter sunk marble tops, backs, etc
2 Dubois plated plug and chain
2 plated self closing Hyde cocks
1 plated rose plug and chain
1 brass cock emptying boilers with waste to baptistry waste
1 galvanized iron smoke pipe and damper to chimney.
3 lead ventilating pipes connected to soil pipe with branches from traps
1 rear basement water closet, etc., complete in working order
Lining baptistry with 14 oz. copper
Move and connect present heater with inch pipes to and from baptistry
Traps, bends, junctions, holdfast, etc., to gas pipes, joints lead ed, left ready for fixtures
State deduction if gas piping be entirely omitted

PLASTERING.

2207½ supl. yards of 3 coats work
188⅔ supl. yards of 1 coat and rendering
16 plaster copetals, moulded, etc
8 foliated copetals, gallery
Supply cotton sheeting to prevent damage by splashing
Large inner face of walls as specified, tight and close to frames
Leave wood work clean for painter, remove rubbish, clean floor, etc., on completion.

PAINTING AND GLAZING.

654 supl. yards of 3 coats painting
1655 supl. yards of staining and 2 coats varnishing
70 supl. yards of 3 coats, picked in bronze
13 supl. yards of 3 coats, blue, bolt heads in gilt
28 supl. yards of 1 coat stain in oil
175½ supl. yards of 1 coat, oil filled, 2 coats, rubbed down, etc
213 supl. yards of 2 coats, painting eaves, gutters, etc
2763 supl. yards of calcimining in 2 tints
600 supl. yards of sheet glazing
Glazing vestry and drawing-room windows with 16 oz. glass, lower panes ground

LEAD GLAZING.

953 supl. yards of lead glazing, soldered and cemented, etc
75 supl. yards of clear lead glazing
172 supl. yards clear glazing loft windows
203 supl. yards of rolled cathedral glazing
100 supl. yards of muffeled cathedral glazing
Providing steel frame ventilators as per elevation carefully fitted

CANADIAN BUILDING STONES.

Peterboro, Ont., June 7th, 1892.

Editor Canadian Architect and Builder.

Dear Sir,—Can you inform me as to the address of the proprietors of the Credit Valley stone quarries? I should think that it would be well for them to advertise in your paper.

Some time ago you promised us a report of a test to be conducted at the School of Practical Science of the different kinds of building stone. I have not yet seen the report, but would like to, as I am desirous of getting information as to where the different kinds of stone could be obtained.

I remain, yours respectfully,

E. Bartlett.

A new system of builders' scaffolds is said to have been invented by a Duluth, Minn., man, who claims that his device will save at least 30 per cent. of the cost of laying brick wall by the use of the present system of lumber scaffolding. The new scaffold is made of aluminum and steel, is light, strong and durable, and is moved upward by a set of simple levers as the wall progresses upward, always keeping the bricklayer's material directly in front of him.

THE LATE W. T. THOMAS.

MR. W. T. Thomas, the well known architect, who died at his late residence, 119 Mackay Street, Montreal, on the 26th ult., was the son of the late Wm. Thomas, architect, of Toronto, who came to this country in 1844, settled in Toronto and was one of the leading architects in the west, and a pioneer of Gothic architecture in Canada, and even on this Continent. His brother, the late John Thomas, won wide distinction as a sculptor and architect, having been chosen by Sir Charles Barry, the architect of the Houses of Parliament at Winchester, to execute the statuary about that building.

The subject of this sketch inherited the family ability, and studied under his father the profession of which he proved himself a master. Mr. Thomas went to Montreal about the year 1864, and for a short time practised in partnership with his brother, Mr. C. P. Thomas, now of Chicago, and subsequently in his own name, rising at once to the first rank among his confreres.

St. George's Church in Montreal, and Trinity Church, St. John, N. B., (both won in open competition), are perhaps the best examples of his genius in Church building, but the many churches which he designed elsewhere, also bear evidence of his ability. Mr. Thomas did not, however confine himself entirely to ecclesiastical architecture, as he executed among other buildings in Montreal, the Caverhill block on St. Peter Street, and the houses of the late Thomas Workman, Lord Mount Stephen and Mr. Duncan McIntyre, the Prescott Town Hall and other buildings throughout the country.

The deceased gentleman leaves a widow, the daughter of the late John Hancock, barrister, of Montreal, and two sons who are studying their father's profession. His funeral took place on the 28th ult. the pall bearers being chosen from the members of the profession in Montreal, viz: J. A. Hopkins, R. C. A.; A. C. Fowler; A. F. Dunlop, R. C. A.; J. J. Brown; James. Wright; W. McLea Walbank.

THE LATE W. T. THOMAS, ARCHITECT, MONTREAL.

SUGGESTIONS FOR THE CONDUCT OF ARCHITECTURAL COMPETITIONS.

SANCTIONED BY THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

1. The promoters of an intended competition should, as their first step, appoint one or more professional assessors, architects of established reputation, whose appointment should be published in the original advertisements and instructions, and whose decision should govern the selection of the designs.

All designs sent in should be submitted to the assessors.

2. The duty of assessors should be:

(*a*) To draw up the particulars and conditions as instructions to competitors, and to advise upon the question of cost.

(*b*) To determine which of the designs conform to the instructions, and to exclude all others.

(*c*) To advise the promoters on the relative merits of the designs admitted to the competition, and to make a selection in accordance with the conditions.

3. Every promoter of a competition and every assessor engaged upon it should abstain absolutely from competing and from acting as architect for the proposed work.

4. The number and scale of the required drawings should be distinctly set forth, and they should not be more in number, or to a larger scale, than necessary to clearly explain the designs. If perspective views be required, it should be so stated, and they should be uniform in scale, number, mode of coloring, etc.

5. Competitions should be conducted in one of the following ways:

(A) By advertisement, inviting architects willing to compete for the intended work to send in designs. The promoters, with the advice of the assessor or accessors, should make their selection for such designs. The author of the design awarded the first place should be employed to carry out the work.

(B) By advertisement, inviting architects willing to compete for the intended work to send in their names by a given day, with such other information as the candidate may think likely to advance his claim to be admitted to the competition. From these names the promoters, with the advice of the assessor or assessors, should select: (*a*) an architect to carry out the work; or (*b*) a limited number to compete, and each competitor thus selected should receive a specified sum for the preparation of his design. The author of the design awarded the first place should be employed to carry out the work.

(C) By personal invitation to a limited number of selected architects to join in a competition for the intended work. Each competitor should receive a specified sum for the preparation of his design. The author of the design awarded the first place should be employed to carry out the work.

6. No design shall bear any motto, device or distinguishing mark, but all designs should be numbered by the promoters in order of receipt. Any attempt to influence the decision of the promoters, or of the assessor or assessors, should disqualify a competitor.

7. In every case the amount of premium or remuneration for the competitive designs should be fixed by the promoters, acting under the advice of the assessor or assessors, and should be paid in addition to the usual professional charges for carrying out the work.

8. Where a deposit is required for supplying the instructions, it should be returned on the receipt of a *bona fide* design, or if the applicant declines to compete and returns the said instructions within a month after their receipt.

9. A design should be excluded from a competition:

(*a*) If sent in after the period named (accidents in transit excepted).

(*b*) If it does not substantially give the accommodation asked for.

(*c*) If it exceeds the limits of site, as shown on the plan issued by the promoters, the figured dimensions on which should be adhered to until officially altered.

(*d*) If the assessor or assessors should determine that its probable cost will exceed the outlay stated in the instructions, or the estimate of the competitor, should no outlay be stated; provided always that, should the assessor or assessors not have been consulted in the first instance respecting the cost, as recommended in paragraph *a* of Clause 2, and should he or they be of opinion that the outlay stated in the instructions is inadequate for the proper execution of the proposed works, the assessor or assessors shall not be bound in the selection of a design by the amount named in such instructions, but the question of cost shall, nevertheless, be a material element in the consideration of the award.

(*e*) If any of the other instructions are violated.

10. It is desirable that all designs submitted in a competition, except any excluded under Clause 9, should, with the consent of their authors, be publicly exhibited after the award has been made, which award should be published at the time of exhibition.

11. The architect whose design may be selected as the best should be employed to carry out the work, and he should be paid in accordance with the Schedule of Professional Practice and Charges of Architects sanctioned by the Royal Institute. If no instructions are given to him to proceed within twelve months from the date of the selection, he should receive adequate compensation in addition to the premium (if any) awarded to him. In the event of a part only of his original design being carried out, he should be paid a sum to be agreed upon in respect of the deferred portion, such sum to be merged in the usual professional charge when the completion of the design is proceeded with.

It should be understood that the Royal Institute issues these suggestions as a guide to promoters where a competition has been decided upon, but not as necessarily recommending the principle of competition.

ASTON WEBB, *Hon. Secretary.*
WILLIAM H. WHITE, *Secretary.*

The Royal Institute of British Architects,
9 Conduit Street, Hanover Square, London, W.
Re-issue after revision, 2nd June, 1892.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

At the regular monthly meeting of the Council of the Province of Quebec Association of Architects held on the 11th inst., Mr. A. C. Hutchinson was appointed examiner in place of Mr W. T. Thomas, deceasde.

The Secretary reported that he had several applications for examination to enter upon the study of architecture and one for final examination.

It was resolved that the Council of the Province of Quebec Association of Architects at this their first regular meeting since the demise of the late Mr. W. T. Thomas, take the opportunity to record their sense of the loss sustained by the profession in the decease of their late respected confrere, who during a practice extending over thirty years, designed so many important buildings that contributed so largely to the advancement of architecture. It was also resolved that a copy of this resolution be forwarded to the widow of the deceased, and that copies be sent to the CANADIAN ARCHITECT AND BUILDER and to the city press for publication.

It was also resolved that Mr. J. J. Brown be appointed a member of the Council to frill the vacancy caused by the resignation of Mr. C. Clift, the Secretary, and the acceptance of the same office by Mr. A. C. Hutchison.

PRESBYTERIAN CHURCH COMPETITION.

THE following is the report of the experts appointed to examine the designs submitted in the recent Presbyterian church competition:

TORONTO, May 31st, 1892.

W. A. LANGTON, ESQ., Registrar O. A. A.

DEAR SIR, – In compliance with your notification of May 6th of our appointment as experts, we have examined the competitive designs sent in for Presbyterian churches, and with much regret we beg to say that in our opinion there is not a sufficiently large number of suitable designs among them to warrant the committee in publishing a pamphlet.

The design for "a country church," under the motto "John Nox" is unquestionably the best of those submitted, that for "a village church," under the same motto coming next in merit, and to the author of these we have awarded the first prize.

Although there is considerable talent displayed in several of the sixteen sets received, there being some excellent suggestions in unfinished drawings, there are nevertheless none, with the exception of the two above mentioned, entirely fulfilling the requirments of the competition, which called for plans of peculiar treatment intended specially to meet the wants of Presbyterian congregations, at the same time having sufficient artistic merit to assist in raising the standard of church architecture in this country. This then being the object of the competition, neither those designs partaking largely of the character of existing buildings, nor those lacking study or of questionable architectural merit, can be said to have attained the end in view, and for that reason such have not been placed.

We respectfully suggest that the premiated designs be kept as a nucleus, and another attempt be made next winter to obtain an additional number of creditable plans.

Yours truly,

FRANK DARLING,
JOHN GEMMELL,
A. FRANK WICKSON,
} Com. of Experts.

The members of the Toronto Architectural Sketch Club are engaged to-day in a cricket match with a local team at Norway.

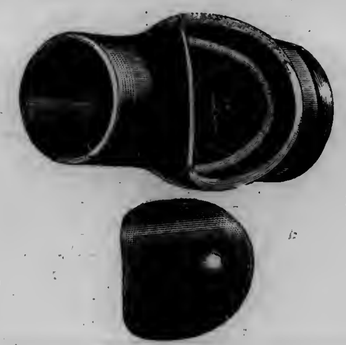
SANITATION AND HEATING

A VALUABLE PLUMBING DEVICE.

Editor CANADIAN ARCHITECT AND BUILDER.

While our plumbing by-law aims at and, perhaps, as nearly approaches sanitary perfection as that of any city, one want has been felt by those who desire to live up to it in the spirit as well as the letter.

When a soil pipe system, including iron drain, has been put in, tested and proved sound, there remains a joint, or rather two of them, and the most difficult of all to make, to connect with the tile drain just outside the building. Though most likely to be defective, there is no chance to test this work, either to see that the inside be clear of cement or the joints gas and water tight. When the tile drain is taken alongside the building to foot of soil pipe, the defects are doubled, and in many hundreds of cases has this been done under our by-law for the want of a simple appliance not in our market, though as a makeshift a T pipe has been used by some plumbers. During my recent travels I was pleased to find an invention, clearly shown by the accompanying cut, known as an "access pipe," and commonly used in England. Having the maker's address, and the price being low, I do not see that we need be longer without it.



In this connection I might also state that in England the practice of laying tile drains corresponds with the national character, ponderous and immovable. A rest is provided under each joint and the whole drain is encased with a solid mass of concrete before covering with earth, preventing any settlement or breaking of joints. The ventilating of traps under fixtures, however, is not common, nor is the plumbing generally equal to ours, though we go to them for fixtures; and I shall be glad when under free or fair trade we may be able to use more of them, as for instance, Shank's porcelain lavatories, as cheap there as the bowl and marble slab, also their enamelled iron baths, more durable than sheet metal and cleaner than wood encased fixtures.

On the continent of Europe good plumbing seems to be unknown, and some of their interesting customs perhaps savor less of decency, according to our standards, than of utility and comfort. In the milder climates, conducive to out-door life, sanitation and house heating, so important with us, can safely be neglected and human energies find occupation in the many fields of art which in this new land remain as yet untilled.

M. B. AYLSWORTH.

VARIATIONS IN PRACTICE*

By H. J. BARRON.

The writer had intended, when starting on this paper, to take some special subject, such as the dimensions of main pipes, or the proportions of risers, but as this is the first meeting at which papers are to be read he decided that glittering generalities might in his case be of more use than solid specialties. The saying that "variety is the spice of life" is not, as it often seems, a flippant remark, but is the most profound philosophy; to differentiate is a necessity of progress and one of the corner-stones

*Paper read before the fourth annual convention of the Master Steam and Hot Water Fitters Association of the United States.

of evolutionary philosophy. In the arts, as in nature, that form best fitted for the environment survives; that which is best absolutely and always no man can say; but that which is worst can be improved by discussion and experiment; the result is knowledge.

Let us commence with estimates: there were eight bidders recently on a Southern post office; A was $9,000, B was $8,500, C was $8,000, D was $7,500, E was $7,000, F was $6,500, G was $6,000, and H, the successful bidder, was $5,500. These are not the exact figures, but those who are conversant with this particular contract will recognize that they are near enough for illustration. As the concerns that bid on this work are familiar with what was required I think if you will add the eight bids together and divide by eight and get the average, you will have a fair bid for the work, which would be $7,275; if you exclude the three highest bidders and strike an average with the five lowest this average bid should be a low bid for the work which would be $6,500; yet the successful bidder is one thousand dollars below this an example of variety with a vengeance.

Recently there was a contract given out in New York in which the bids ranged from $9,000 to $11,000. There were seven bidders. The owner of the building was a business man without preferences—except preferring to get the most for his money. There was to be furnished 6,500 feet of surface in direct radiators, two 75 horse power tubular boilers, with everything that goes into a plant of this character. In this case the lowest bidder also got the work, and the other bidders, who had spent their time advising and negotiating with the owner, got something to think about.

In alluding to this subject I feel like apologizing, as this is such an old, old story, but it is one that a little discussion of may prove interesting. In regard to details one concern makes full working drawings for all work and gives the steam-fitter a specification to work from; others have the foreman lay out work and dispense with drawings, except the use of the architects' plans, perhaps; one concern cuts all its pipe to dimensions in the shop—risers, mains and everything; other concerns cut everything on the job, the largest as well as the smallest pipe; others again pursue a middle course, cutting all pipe above 2½ inches in the shop and all below that size on the job; one concern sets its boilers with a return flue over the top (I am now speaking of the ordinary return tubular boiler); another condemns this practice; one lines the fire-box back of the bridge wall as well as in front of it with fire-brick; the majority only line in front. A & Co. have domes on all their boilers; G & Co. never use them. X uses a straight bridge wall, and H uses a curved one. J feeds through a top feed, and K through the blow off in the back. Then with size of main pipes (I am now speaking of an apparatus with reduced pressure and exhaust combined, say, with 5,000 feet of radiator), B starts the steam main with 4 inches and ends with 2 inches, while C starts with 6 inches and ends with 3 inches. C has a 3-inch return main, and B a 2-inch. X uses a reducing valve the full size of his pipe without a bye pass; C puts in a bye pass and uses a reducing valve half the size of his pipe, while H uses a bye pass half the size of his pipe and reducing valve full size. X uses a pump governor to control the pump returning condensation; C uses a drip tank and lets the engineer control the pump; X puts on a noiseless back pressure valve, and C puts on an ordinary one; one uses a separator on his steam pipe to the engine and a grease extractor on his exhaust pipe to heating system; others leave them off; one uses a continuous main pipe dripped only at the end, while the other has a drip from every riser. Shall we run a steam riser and a return riser and an air line, and how shall we connect our radiators? Shall we run the three risers, and on every floor where we take out a radiator connection run all around to the far end of the radiator, even on the second floor as on the top, to allow for expansion? Shall we use the single or double pipe? Shall we run an air line? Shall connections to radiators be taken above the floor or beneath it or under the ceiling? Chicago takes them above the floor, New York beneath the floor and Buffalo under the ceiling. A curious thing about Buffalo practice is the single pipe system with two valves on the radiators. The two-valve single pipe system, as it is called, this is equalled by a well known concern that puts a single valve with the two-pipe system, a double riser and only one valve on the radiator, and in Philadelphia they put a check valve on the return end of the radiator, using the double pipe.

The writer's creed, as a steam-fitter, is about as follows:

1st. I believe the water tube boiler superior to the fire tube.

2nd. I believe the sectional radiator superior to the solid base radiator.

3rd. I believe the single pipe system superior to the double pipe for all purposes.

4th. I believe every high pressure or reduced pressure apparatus should have a pump governor and also a boiler water level regulator.

5th. I believe in an open feed water heater.

6th. I believe good steam heating is better than good hot water heating, and that there is more skill required for the design and erection for the best steam heating than there is for the best hot water heating.

7th. I believe the hot blast system or, as it is sometimes called, the fan system, is the proper system for public buildings.

8th. I believe every exhaust pipe should have a grease extractor and every engine pipe a separator.

9th. I believe a steam dome on a tubular boiler an absurdity.

10th. I believe it requires an exceedingly clever man to be the lowest bidder and make his business pay and acquire a reputation for good work.

In conclusion let us hope there will be always variety enough to make the life of the thermic engineer interesting.

MANUFACTURES AND MATERIALS

A company is being formed at Waterloo, Ont. for the purpose of constructing asphalt pavements.

Messrs. Fitzgerald & Minhinnick are forming a joint stock company at Hamilton, Ont., with a capital of $50,000, to manufacture ornamental tiles for architectural purposes.

The Trinidad Asphalt Company, of Toronto, limited, has been incorporated with a capital stock of $100,000, divided into one thousand shares of $100 each. Charles Riordan, A. Scott Irving, John Ellis, M. J. Adams, W. M Hall and M. F. Brown compose the company.

The Laprairie Pressed Brick and Terra Cotta Company is being organized, with a capital of $150,000. The promoters are: Messrs. Peter Lyall, of Montreal, Hugh Cameron, of Toronto, Archibald Dunbar Taylor, of Montreal, Thos. Auguste Brisson, of Laprairie, William Johnson, of Montreal, Thomas Henry Rothwell, of Goderich.

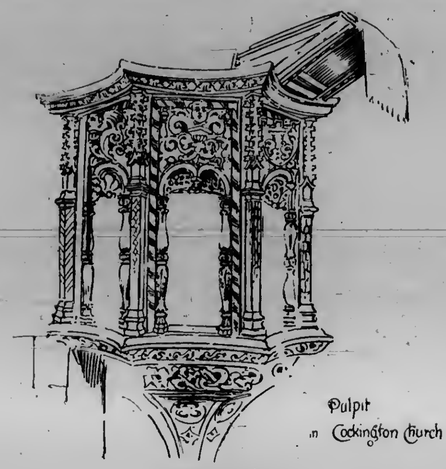
Mr. Cranston A. Stark, of Winnipeg, has recently patented an artificial stone paving tile or block, composed of Portland cement and sand, made plastic with water, and comprising two layers, one layer consisting of equal parts of cement and sand, and the other layer two parts or more of sand to one part of cement, both layers united by pressure in a plastic state in a mould forming the shape of the tile.

Application has been made for letters of incorporation for the Kramer-Irwin-Roach Asphalt and Cement Paving Company (limited), of Hamilton, with a capital stock of $10,000. The proposed incorporators are: Herman Kramer, Buffalo, and Thomas Irwin, John T. Irwin, W. J. Kingdon and J. F. Monck, of Hamilton. The object of the company is to construct pavements of German asphalt, and it has applied for and received permission to lay down a specimen piece of roadway so that citizens may have an opportunity to judge of its merits.

E. B. Butterworth, Ottawa, Ont., has been granted a patent on a warm air furnace, which consists of the combination of a fire pot having angular corrugations, some of which have their edges extended to form flanges, an oblong base, containing grate, ash doors, and draft damper, cylindrical combustion chamber, having a shell consisting of angular corrugations provided with fire door and down flue, a conical top or dome, a deflector suspended from said dome, a down flue attached to the combustion chamber having branch, with damper; a radiator attached to the down flue and partly surrounding the fire pot, branch pipe attached to said radiator and provided with check damper, and the pipe rising from the branch and connected with the branch and the enclosing casing.

As far as research has been able to determine, glass was in use 2000 years before the birth of Christ, and was even then not in its infancy by any manner of means. In the Slade collection of the British museum there is a head of a lion moulded in glass, bearing the name of an Egyptian king of the 11th dynasty. This is the oldest specimen of pure glass bearing anything like a date now known to exist. The invention now known as "bleezing," the mode of varnishing pottery with a thin film of glass is believed to date back to the first Egyptian dynasty. Proof of this is found in the pottery beads, glass glazed, found in the tombs of the age above referred to. Dr. Schliemann found bits of glass in his excavations at Mycenæ, though Homer does not mention it as a substance known in his time. The most eminent Egyptologers place the date of the first use of glass at a period too remote to be given in years.

DECORATION AND FURNITURE



Pulpit in Cockington Church

DECORATION.*

And now, to come to my special subject, I will give some hints as to the best manner of treating a middle class dwelling, and will begin at the entrance hall. Of course there are many ways of dealing with this, as with every other part of the house, so I must give several modes of treatment. It has long been the custom to treat the hall and staircase as unimportant parts of the house, to give them little or no attention, and so they have presented a naked, cold, and uninviting aspect—places to be hurried through as quickly as possible. The ceilings have been left white, and the walls painted one plain unbroken tint of drab or stone color. The visitor obtains his first impression of the house on entering the hall, and it is desirable he should be well impressed. We may first consider the ceiling. It should not be pure white, as garnish whiteness is out of accord with all other coloring—that is, in connection with house decoration; the whiter your shirt-fronts are the better. Well, the ceiling may be painted some shade, such as light vellum or fawn color, or some shade of blue, neutral in tone, such as the shade presented in the duck egg shell. The ceiling tint will be regulated by the coloring of the walls. This toning of the ceiling is good as far as it goes, but there is no limit to the various ways it may be decorated. Stencilled ornament is one of the less expensive modes. And here, in speaking of stencilled ornament, it must not be thought that this is necessarily a "cheap and nasty" mode of ornamentation because we are all familiar with wretchedly designed and executed work of this kind. A stencil is a design cut in firm paper, cardboard, or tinfoil, and the color is stamped through the openings in the manner of printing. Now all printing is not artistic, yet the capital letters in old Italian and German books are full of artistic design yet they are printed, too. So with the stencil plate. It first of all has to be designed, and the highest powers of draftsmanship may be brought to bear in the production of high-class stencil work. The same design may be traced directly by hand, but the stencil plate is used as a quicker method of obtaining like results. The reason why so much work of this kind is inferior is simply because it is difficult to do it well. Preston Town Hall, in England, decorated by Heaton, Butler and Bayne, the eminent glass-stainers and decorators, is nearly all stencilled work, but yet it is one of the best decorated halls in England. I do not recommend stencilled in place of hand-painted work; where money is forthcoming, I prefer to do the latter. But to return to the hall ceiling. It is a simple and inexpensive way of getting a pleasing effect to put a band of well-designed ornament round the ceiling, its breadth being regulated by the size of the vestibule or hall, and there is no reason why the centre of the ceiling should not be covered with a simple geometrical design in quiet colors, and treated flatly, without light or shade. A little gilding introduced in small spots and thin lines defining the leading forms of the diaper or panelling has a very good effect, but there is no limit to the richness and quality of design that may quite fitly be expended here. Besides that, there are many alternative modes of treatment besides painting. There are beautiful paper hangings specially designed for ceilings, besides several embossed or raised materials such as Tynecastle tapestry, Anaglypta, and Japanese leather papers, which when harmoniously colored produce most pleasing effects. The cornice should be colored to connect the ceiling and walls, care being taken to use light shades where the mouldings and enrichments are delicate. The treatment as to the division of the walls will depend on the height of the ceiling, but generally speaking it is good to put a frieze under the cornice, and it is useful to have a dado here, and in the staircase following the rake of the handrail. The dado and wall space should be separated by a wooden moulded rail. The dado should be highly varnished, so as to allow of washing and dusting without the risk of soiling. The color of the walls should be pleasantly warm, such as terra-cotta, or even Pompeian red, the dado in deeper shades of the wall color; soft olive green is also good for staircase walls. Blue, unless it is of the peacock shade, or approaching a grey green, had better be avoided here. The steps of stairs if of wood, should be stained a deep walnut color, or if they be of stone they may be painted a deep shade of the dado color, and varnished to allow of cleaning frequently. The hall and staircase walls may be papered there are special designs made for the purpose that look very well indeed, having friezes and dadoes specially colored to match. The hall is a good place to hang etchings, autotypes, and engravings, in quiet oak or black moulded frames; and when they form a special feature of the decoration, the walls should be painted a quiet shade, as a florid patterned paper detracts from the value of the pictures. The carpets and portières should be in strict harmony with the decorator's work, and should be chosen by him or the architect. I have often seen the whole harmony of coloring in a house destroyed by the unskilful selection of the carpets and hangings. The woodwork should be painted in one or more shades of maroon or other rich brown colors and varnished, all graining should be avoided. I must confine myself to broad principles as I proceed, as I could multiply varieties of treatment without end. The dining-room should be sombre in tone, the ceiling a vellum color in depth to suit the walls. It may be divided by wood mouldings into geometrical panelling, and these panels filled with Tynecastle tapestry or Anaglypta, the effect of this is as if it were executed in low-relief plaster work. The designs manufactured now are very beautiful. If the ceiling is treated in this manner, the walls may also be decorated with the same materials, for there are friezes and wall hangings made of the same stuffs. The painting and gilding on those surfaces can be as simple or as grand as may be demanded, they are capable of many and varied beautiful treatments. Immediately under the frieze should be fixed a moulded picture rail; this is much better than a metal rod, as it goes round the entire room as the cornice does; its distance from the cornice will depend upon the height of the walls. The advantages of lowering the picture rail is that it affords greater ease in hanging the pictures, and prevents the unsightly cords being seen to the same extent as when going to the cornice; by shortening the cords, too, pictures hang steadier and the chances of breakage are lessened. This moulding can be colored to be in harmony with the walls and rendered almost invisible, or it may be gilt solid so as to form a marked boundary to the frieze. The coloring of the walls should have reference to the pictures, and should not be too light in tone; experience has discovered that dark reds or old gold color, not unlike rich brown paper or dull tones of green, either cool and grey, or warm and brown, are the best for showing pictures to advantage. I painted the dining rooms of two of the Royal Academicians in London, J. Pettie's and McWhirter's, and in both cases the color selected was a dark grey-green; both artists found the full value of the coloring of their pictures brought out to the fullest extent on this dark background. The Royal Academy walls are colored a dark Indian red, and so also are the walls of the British National Gallery. As chairs are placed round the walls of the dining room, it is good to put a chair-rail at the height of the chair-backs; this prevents the chairs from breaking the plaster. The dado should be colored in relation to the walls above, and a good many shades darker; the dark dado takes from the bareness of a large room, and gives a coziness and furnished appearance which does not exist when you can see each piece of furniture clearly defined against the walls. The woodwork should be painted good solid colors of Indian red or walnut shades, or black and resembling ebony. I do not recommend decorating the panels with any kind of natural flower designs; thin flat hand-painted ornament in ivory color, resembling, but not imitating, inlaid work, is chaste and beautiful. If the wood is of good quality the panels may be decorated with various stains in full and rich designs as shown in samples here. I have decorated the saloons of many of the great ocean steamships in this manner. It is best to French polish surfaces decorated in this way.

As yet I have dealt with the ceilings and walls as covered with embossed materials, either in low or high relief. The ceilings, where dust cannot settle, may safely have the designs in high relief, but those in low relief are more suited to the walls. The walls themselves may be formed into well proportioned panels, not so small as to interfere with the placing of the furniture or the hanging of the pictures. The panels should be divided by wood mouldings and there should be a style round each treated in flat tints of such a kind as to show the panel colouring to the greatest advantage. The French are partial to the mode of treatment, and I think it a very good one; it gives a rich furnished appearance to the walls. Both ceilings and walls may again be oil-painted and decorated in a hundred ways; I have painted many of the finest houses in Scotland in this way, the ceilings being entirely decorated by hand with figures, wreaths, and ornamental compositions, the walls also being decorated with the like specially designed and hand-painted ornament. This is the most artistic manner, and no two houses are ever painted in the same way. Of course, ordinary wall papers may be applied here as everywhere else in the house, and if chosen by an expert, very fine effects may be obtained in this manner. I don't think there is a wiser way of spending money than in making the home beautiful. Our wives and families spend most of their lives at home, and the enjoyment derived from beautiful surroundings is beyond estimate, besides the refining influence it has on our children. There is no pleasure so constant, so soothing, so lasting and elevating as that afforded by a lovely home; it

*Abstract from a paper read before the Sydney, N. S. W., Architectural Association, by Mr. Andrew Wells.

is the most unselfish pleasure, too, as all our friends may share it. In a room where there is heavy furniture it is good to have a margin of say 30in. round the floor uncarpeted, so as to allow of the carpet being frequently taken up and shaken. This margin may be painted in some dark shade agreeing with the carpet and dado, or if the floors are new they may be stained to a dark oak or walnut color, and in both cases varnished. Wax varnish is most artistic in effect, but is more liable to soil and takes much more labor to keep in good order, and parquet flooring is better than either of the former, but is more expensive.

The drawing-room is the ladies' special room, and should be bright and cheerful. It is difficult to deal with a subject like color to make you realize effects from mere description, and to describe in detail the many ways I could treat a drawing-room would merely confuse you, so I will be general in my remarks. All the materials described for the dining-room treatment would be applicable for the drawing-room. The dado is not so necessary here, as the chairs are not usually placed against the walls, and instead of the sombre hues suited to the dining-room, soft quiet, and light effects are best —say cream or soft duck-egg shell blue or French grey for ceilings, the walls fawn color or a richer French grey or a deeper grey blue, approaching peacock shade. All these are good for showing ladies' complexions and dress to the best advantage, and that is a consideration not to be overlooked. Water-color drawings will also look well on these grounds. The woodwork may be cream-white finished with enamel varnish; this gives a beautiful smooth and fresh effect. I think the judicious application of gilding in this room very advantageous, but the same remark applies to all the public rooms and hall. I think it is better to gild the small enrichment of cornices solid than to break up the ornament of the large enrichments with points of gold what is technically called "hatching" or "picking out." The round, the concave, and small ogee mouldings always look well gilded, as their rounded surfaces catch the light from all points. The wall should be decorated with water-color drawings or etchings tastefully arranged. Choice pieces of Oriental and Doulton pottery are beautiful and very decorative. I have fitted a narrow moulded shelf, supported on neat brackets, all round the walls except where occupied by cabinets about 4 ft. high from the floor; this shelf having a groove on the upper surface for holding plates and photos—this is to prevent them from sliding and is a very pretty arrangement, as between the photos pretty pieces of pottery and statuettes may be placed. Above this shelf should be hung the water-color drawings, etchings, and engravings; or, instead of this narrow shelf, dwarf book-cases rising 3 ft. high may be put round the room, and on the top of those the photos and ornaments may be placed. Books in themselves are very decorative in effect, besides the delight of sitting in rooms supplied with plenty of them. I think there should be many books in the drawing-room; it is the general sitting-room, and no one need ever be weary or suffer *ennui* who loves good books.

The morning-room I will not describe further than to say it should be light and cheerful and cool in tone. French greys and light hues are good. It may be painted entirely and decorated in a simple manner, or any of the wall coverings may be used here quite fitly.

The library is better to be subdued in tone, but not gloomy. The wall should be the background for rare prints and etchings, so should be painted or, if paper, some old rich leather effect is good with a pattern not over conspicuous, the ceiling and cornice colored to match and the woodwork as in the dining-room, dark and decorated with thin lines and ornament. The books should be easily accessible, and low book cases not more than five feet high or lower look very well. I think it is better to have no glass in front of the books, except to protest the rarest of very valuable ones. I have observed that those placed beyond reach of the hand are rarely opened. The floor should be stained or painted all round, say one foot in front of the book cases, so that carpet or rug may be lifted without disturbing the book-cases.

The bed-rooms should be dealt with as to color according to aspect, those getting much sunshine should be cool, and those in the shade warm in tone. I think it good to paint the ceilings and walls of bed-rooms. The walls may be finished with a dull gloss, the paint being partly mixed with varnish; this allows of their being washed down without injury to the paint, and insures that they be always fresh and clean. Walls painted in this manner will last a life-time. The walls and ceilings may be perfectly plain, but there is no reason why the ceilings may not be decorated in a simple way with lines, borders and corner ornaments, or even in a fuller manner. In the children's rooms it is as well to have dadoes that may be fully varnished; of course the walls may be papered without any breach in the fitness of things, and lovely papers are to be had in plenty, and some are made purposely to allow of sponging down. They are called sanitary papers, they are quiet in color and very serviceable. The woodwork should be painted to suit the walls, generally in light tones, and if varnished so much the better; it lasts much longer and all finger marks can be easily wiped from it. I think it is best to oil paint the ceiling in all cases, it lasts for many years and is easily cleaned, and if renewed can be done without causing the dirt and mess that distemper always produces, when washed off. The margins of floors should in all cases be stained or painted and varnished, so that the carpets may be frequently shaken; freshness and cleanness in bed rooms is of the utmost importance. For the same reasons the kitchens and offices should be oil painted, and not distempered; the paint can so easily be washed down by the servants, and it lasts so much longer than distemper, that the difference in the first cost is soon made up. Here the woodwork should be varnished, and the walls for 5 ft. up the same; a simple line should be drawn at the top of the dado.

For the outside of cemented houses there is no treatment that so effectually resists the entry of rain as to paint the walls thoroughly, and when applying the last coat to powder them with fine dry sand. When dry this makes so hard a surface that water cannot penetrate it; it is more costly than ordinary painting, but it is practically imperishable, and so cheaper in the end. As to the best colors for outside painting, I don't feel that any hard and fast rule can be laid down. All tones of stone color, from cream, yellow to terra-cotta and dark chocolate, may be used. I would avoid shades of green and blue on the cement, except they be very neutral in tone; from white through yellow tones to dark red and brown are the most suitable shades. When the walls are painted dark colors, then the window sashes and verandah should be made very light, say, white tinted with yellow, green or blue or even pure white; on the other hand, if the walls are painted in light colors, the window sashes and other outside woodwork may most fitly be painted in dark shades, say olive green, Indian red or dark peacock blue.

The above is a very general survey of the house, but, perhaps, as much as can be profitably introduced into an hour's lecture such as this. It is impossible to do more than treat the subject on the broadest lines. I am embarrassed with too much matter rather than with too little, for practically there is no limit to the modes of treatment for every part of the house. I am far from thinking there is only one good way of painting houses; there are many. For instance, if character is wanted, the house could be treated in purely Greek design—or full of refined designing and affording scope for full harmonious coloring. The Renaissance is founded on the Classic, but treated with abundant freedom and grace by the Italians and other European nations. The various French developments of the Renaissance have their own beauties: Louis Quinze and Louis Seize are full of character, lightness and elegance. But while I have seen much of this high-class work, and executed some, the ever-present regret one feels in the colony is that so little of it is in demand. The country is probably too young, and feels itself bound to be content with humbler things until it can afford better. But of one thing I do complain: it is the system of tendering for every kind of work. Every contractor is assumed to be equally able to do artistic work; cheapness is held to be the criterion of merit and not quality. Things are different in England. A man of merit there is treated with respect, and his worth is acknowledged. I suppose things will improve here as we develop a richer and more leisured class. As this class grows, so the appreciation for Art work of every discription will grow with it—a consummation devoutedly to be wished!

The following two cements are of considerable value in caulking hot water pipes: (1) Two parts of ordinary well-dried powdered loam and 1 part of borax are kneaded with sufficient water to a smooth dough, which must at once be applied to the joints. After exposure to heat, the cement adheres even to smooth surfaces so firmly that it can only be removed with a chisel. (2). Mix 430 parts by weight of white lead, 520 of powdered slate, 5 of chopped hemp, and 45 of linseed oil. The two powders and the hemp, cutinto lengths of about ½ in., are mixed intimately, the linseed oil gradually added; and the mass is then kneaded until it has attained its uniform consistency. It is claimed that the preparation keeps better than ordinary red lead cement.

A practical plumber, in a communication to a foreign contemporary, considers that the best working solder for plumbers is made of two parts of pure lead and one part of tin, and to test its quality he would well stir the solder in the pot, and then take a ladleful out and pour it upon a clean dry, level stone, and if the metal has a dull white appearance on both sides, it is too coarse, and needs additional tin; if the metal is closely covered with spots, it is a sign there is too much tin in it; but if the metal has but few spots here and there upon the upper surface, it will be in good condition.

CANADIAN ARCHITECT AND BUILDER.

VOL. V.—No. VIII. TORONTO AND MONTREAL, CANADA, AUGUST, 1892. PRICE 20 CENTS $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),
PUBLISHED ON THE THIRD SATURDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.
C. H. MORTIMER, Publisher,
14 King Street West, - TORONTO, CANADA.
64 TEMPLE BUILDING, MONTREAL.

SUBSCRIPTIONS.
The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.
Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.
Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should always give prompt notice of same, and in doing so, should give both the old and new address.

NOTICE OF REMOVAL.

On or about the 20th of September, the publication offices of the CANADIAN ARCHITECT AND BUILDER will be removed to the new Confederation Life Association Building, corner of Yonge and Richmond Streets, Toronto.

IN connection with the publication of the competition design for a suburban house in our last issue, we omitted to print the name of the author, Mr. W. Ford Howland, Toronto.

THE project for connecting Prince Edward Island with the mainland by a sub-marine tunnel is assuming practical shape. At the last session of Parliament, $12,000 was appropriated to cover the cost of making preliminary surveys. Borings for the approaches on the island have already been made, and the character of the rock is reported to be favorable for tunnelling.

PUBLIC recognition of architectural ability is of rare occurrence. An instance of such recognition, however, is at present seen in the determination of the trustees to place in the library of Cornell University a portrait in oil of the architect of the building, Mr. W. H. Miller. The painting of the portrait has been entrusted to a Canadian artist, Mr. J. C. Forbes.

THE members of the Chicago Architectural Sketch Club have been invited to submit designs in a competition for a permanent memorial monument to the late J. W. Root. The memorial is to cost $15,000, and is proposed to be erected in Jackson Park. In view of Mr. Root's ability as an architect, and his popularity, especially with the younger members of the profession, this competition should awaken much enthusiasm, and call forth the best efforts of which the members of the Club are capable.

A SYNDICATE, in which some Toronto persons are interested, has been formed to manufacture steel by what is known as the Hastings process. The surprising claim is made that by means of this process structural and cast steel adaptable for all purposes can be manufactured from pig iron at a cost of a few cents per ton. Such a discovery might be expected to give an impetus to iron production in Canada and greatly cheapen the cost of the construction of large buildings in which iron and steel are so largely employed.

REFERRING to the death of the late W. T. Thomas, of Montreal, the *American Architect* states that he was "still in the prime of his usefulness, being only sixty-four years old at the time of his death," and adds, "but our harrassing and poorly-paid profession does not favor longevity in those who practice it, and we can perhaps hardly say that he was too soon released from his anxieties." Without disputing the fact that the practice of architecture is usually attended with many vexations and much mental anxiety, it nevertheless appears to us anomalous that our contemporary should have selected as an example of the effect of these influences one who had almost attained to the allotted three score years and ten. It should be borne in mind that the men who live beyond sixty years, are largely in the minority.

THE Toronto City Council has foolishly allowed the opportunity to pass of securing, at a moderate cost, the enlargement of the space for traffic at the corner of King and Yonge streets. The owner of the old building on the north-east corner has recently replaced it by a new structure, which, although not of an

expensive character, will add perhaps $15,000 to the cost of the site. Since the erection of this building, which is five or six stories in height, the lack of space at this point has become more than ever noticeable, and an idea can easily be formed of the condition of affairs which will exist when a similarly tall building shall have taken the place of the low one at present occupying the north-west corner. There is no wiser step that the Council could take on behalf of the city's future than to still endeavor to provide for the carrying out of this improvement, even at the extra cost which the erection of the new building to which we have referred would entail.

THE architects of Australia are to be congratulated upon the announcement recently made that the law compelling registration, for the passage of which the leading men in the profession have been laboring for some time past, will be introduced as a Government measure on the opening of parliament. Under these circumstances its passage in some form may be considered assured. On the other hand we regret to observe that the bill providing for the registration of architects in the state of New York, after having passed the legislature, has been disallowed by the Executive, in compliance with the petition of five New York architects, none of whom are members of the American Institute of Architects, or have attained to distinction in their profession. It is not a matter of wonder that the decision of the Executive has awakened a feeling of indignation on the part of the professional press and of those who have put forth unremitting efforts on behalf of the measure.

THE principal business thoroughfares of Toronto are being torn up to permit of the laying of companion water mains and permanent pavements, and the putting down of tracks for the electric street railway. The excavation, close beside the fashionable promenade on King street, let loose into the atmosphere noxious gases and foul odors to such an extent as to cause pedestrians as far as possible to avoid the locality. The underground conditions thus revealed are not pleasant to contemplate. The earth appears to be completely saturated with illuminating gas and other substances which are continually being discharged from defective mains. These substances, so deleterious to health must find their way into the atmosphere of the streets, and into cellars, where the results are still more harmful. Another thing which a glance into these excavations suggests, is the liability of frequent accidents to the network of pipes buried beneath the surface of the streets. It seems almost too much to hope that the permanent pavements which are about to be constructed will remain long undisturbed.

UNUSUAL dullness prevails in the building trade in Toronto, the result to a large extent of operations having been carried on for several years past on much too large a scale. Hundreds if not thousands of houses were erected by speculative builders in advance of the demand. Many of the houses so erected in the expectation of a speedy sale, were put up in a most unsubstantial manner, and by the time the population shall have increased sufficiently to create a demand for new buildings, will have become scarcely habitable. The work under way and in prospect is principally of a commercial character. Many of the large structures, such as the Confederation Life Association building, the new University buildings, Victoria College, Ontario Legislative buildings, etc., which employed much labor and material, are nearing completion. It is to be hoped that the services of the workmen on these structures will be in demand for the proposed union railway station, the new city buildings, drill shed, etc. It is also to be hoped that the proposal to erect a first-class hotel will soon assume tangible form. The city is much in need of such an hotel, and whoever may carry out the undertaking will no doubt receive ample return from the capital invested.

THE architects of Germany have appointed a committee to arrange an architectural exhibit for the World's Fair. About two hundred of the most meritorious buildings in all classes erected during the last decade have been selected by a competent jury, and special invitations sent to the architects of the same to forward the necessary drawings. The Government will defray all charges for transportation, insurance, etc. December has been fixed as the time when all drawings for the exhibit must be ready. The attention of Canadian architects was recently called to the importance of taking immediate action to insure a creditable exhibit of Canadian work. Our German friends, who, are generally supposed to move more deliberately than the people of this continent, are at least far ahead of us in this matter. The influence of their example should cause us to awake from our seeming lethargy and act promptly in a matter of such importance. Why should not committees be at once appointed by the Associations of Ontario and Quebec to deal with this matter? Since the above was written we have received from the Secretary of the Committee on Congress of Architects a request for the names of members of the Canadian Associations of Architects. It is intimated that the names of architects throughout the world are being collected preparatory to issuing a call for an Architectural Congress to meet during the Columbian Exposition. The practical objects of the congress are stated to be to bring the leading architects of the world into fraternal relations for mutual acquaintance and the promotion of their mutual interests, to review the progress of architecture in different countries and by a comparison of results attained promote the general advancement of the profession of architecture throughout the world; and to consider the principles of architectural art and the relations of architecture to the other arts, sciences and industries.

THE destruction a second time of the city of St. John's, Newfoundland, will, it is to be hoped, lead to the erection of buildings of more substantial character, capable of resisting to some extent the action of fire. The greater part of the city having been built of wood, it was impossible for the few substantial buildings to withstand the intensity of the flames on every side. We are informed that the fire protective service was sadly inefficient, but the most perfect system could be of little value when once fire had got possession of a street of wooden structures. St. John's being the only city in the colony was the site of a number of costly public buildings, most of which were destroyed. Among these were the Government House, erected at a cost of a quarter of a million dollars, legislative buildings, custom houses, hospital and market buildings, court-house, chamber of commerce, commercial bank, Temple Club house, Masonic Temple, Athenæum Buildings, Methodist college, St. Andrew's church, and the two great cathedrals, Roman Catholic and Episcopalian, which are said to have cost in the neighborhood of $1,000,000. From the *Building News* we learn that the latter of these cathedrals had been some five and forty years in course of erection in sections. The original designs were prepared in 1847 by Sir Gilbert Scott, and the nave was then erected. In 1880 the next step was taken, when the choir and transept were built by masons sent out from England, under the direction of Mr. Gilbert Scott, to whom was entrusted the completion of his father's designs. The whole of the freestone was exported from Scotland. At the time of the fire the cathedral consisted of a nave with aisles of six bays, lighted by a single lancet headed window in each bay of the aisle and clerestory, and a western narthex; projecting transepts and a square-ended choir of four bays, this eastern work being of fully developed Decorated character, and provision was made for a future central tower, 35 feet square with broach spire. The styles were purely worked out, the whole effect being simple and bold. The Bishop of the diocese is soliciting funds in Canada and Great Britain to aid in the reconstruction of the edifice. A similar appeal is being made for funds to rebuild the Methodist college. The total insurance on property destroyed is understood to amount to about $6,000,000. Some of our architects and builders who are not at present overburdened with work might find in St. John's a profitable field for their energies.

THE crowds of busy citizens who throng our business streets suspect but little, if they think of them at all, the dangers that are near them through the insecurity of many old buildings, arising from careless and cheap construction in the first place, weakened by the hand of time. And generally it is not until some alterations to existing premises, such as tearing out of shop fronts for the purpose of putting in larger windows, are taken in hand, that the real truth concerning these structures, is exposed to view. But every now and then we are startled by the exposure, and we wonder where our building inspectors are,

that they do not warn off the foot passengers and insist on a protecting hoarding. There is this to be said against a hoarding, namely, that it would not be of very much use if the buildings in question chose to come down with a run. A short time ago on King street opposite the cathedral, Toronto, the cornice and freize of an old shop front was removed, and behind it was discovered, not the usual horizontal beam, but a laminated beam cambered to a foot or fifteen inches and tied in with a tie rod at the feet. Whether any test was applied or not to the tie rod, which was in place for a number of years, we do not know, but we are inclined to think not. In a couple of weeks, a two-story brick wall was built on the top of the "beam." Every one knows that the rust gets at iron, even under paint, and we are inclined to question very much whether, if the houses on either side of the one in question were removed, the cambered beam would be held in by the rod. We should expect to see it "kick," and the whole construction descend. At the time of writing there is an exposure of even more alarming character, because absolutely unaided in its ability by neighboring buildings, this is where a shop front has been removed on the north side of King street between Toronto and Yonge streets. Here we see a 12″ × 12″ beam of about 18 ft. long, with one end resting not more than 2″ in a brick wall, and that not on a plate or cushion, but upon a single brick; the other end of the beam is not seen. Two 4″ iron columns support the beam at say 5 ft. or 6 ft. intervals, and on the top of the beam is some of the roughest brickwork, laid anyhow, some bulging out to the street, some canted, and all apparently loose, which description answers also to the pier into which the end of the beam is supposed to be "built." Over this miserable brickwork rises two stories of better brickwork, but although the danger is so excessive and so apparent, nothing is done day after day to prevent what may perhaps be a serious calamity. There is a tie rod running at right angles from the end of the beam through about eight joists set parallel with the beam, which appears to have its end in a trimmer arch, but there can be no great help expected from this tie rod, as it is passed through the joists on a curve and is not by any means tight. No doubt now that the discovery of this weakness has been made, its defects will be remedied, but how about those buildings concerning which no alterations are contemplated? Surely these exposures should warrant our inspectors making an examination of all our old buildings, which, so far as we can see, is the only way to avoid some serious accident. The need of a vigilant system of inspection has been further emphasized since the above was written by the falling in of the roofs of a row of five houses on Florence st., Toronto, on July 30th. Only three of the houses were occupied, and fortunately the inmates escaped with but slight injuries.

PROVINCE OF QUEBEC A. O. A.

The annual meeting of the Province of Quebec Association of Architects will take place in Montreal on Thursday, the 29th of September.

The following are the names of the successful candidates in the recent examinations of the above Association: L. Lemieux; Fred. Loomis; M. W. Hogle; D. MacFarlane.

TEMPERING STEEL TOOLS FOR STONE WORK.

The matter of tempering drills and other tools for stone work is one of so much interest to quarrymen, that we may be pardoned for giving at length the very able paper on the subject presented by the *Northwestern Mechanic*. We add to it only this advice, "Stick to a single brand of steel," and let your blacksmith get thoroughly acquainted with its properties. There may be several brands of equally good steel, but they must be worked separately, and with a full knowledge of their peculiarities. That failures occur are more often due to the peculiarities of the steel than to the ignorance of the blacksmith, and if the blacksmith is ignorant in a specific case, it is because he cannot know the properties in every brand of steel. However the article contains its own comment:

In sharpening drills for stone work, the first thing to guard against is not to heat the steel too hot. All the books treating upon this subject say, "never heat above a cherry heat." This is certainly a safe rule to work to, but it does not apply to all varieties of steel. Some kinds will bear heating to a bright red heat, and still others will bear a yellow color without detriment to the metal. In all cases the steel should be worked as hot as it will bear, notwithstanding the old advice "to forge at as low a heat as possible." The forging should be done at as high a heat as the steel will bear, but the finishing should be done at a very low heat, and it is better to hammer the drill until the heat is out of sight and the metal becomes black. For such hammering the blows should be light, and very little drawing of the metal should take place. Heavy blows upon a cold or nearly cold piece of steel will cause the particles of the metal to move over each other, ending in disintegration of the metal.

Cracks often develop after steel has been hammered too cold, or rather after it has been hammered too much while nearly cold.

Suppose that a common ¼-inch drill is to be made for use in making holes for plug wedges. Select a piece of ¼-inch octagon steel; cut off a piece 24 inches long, which is just enough to make two good drills. Heat one end of the piece for about six inches in length, drawing it down to ⅝ of an inch; then hammer it octagon, and still further reduce to a little over one half inch. A swage should next be placed upon the anvil, the drill placed therein and operated upon by a top swage and sledge hammer. Draw down to a little more than ½ inch. Take care to make a fine taper at the point where the octagon shape merges into the round part of the drill. This taper should be about two inches long. Take care that the round part of the drill is exactly central with the large part; an overcast at this point will result in making a poor tool. All instruments to be used by percussion must be perfectly straight from one end to the other, otherwise they will spring when struck by a hammer, and a large portion of the force of the blow will be lost, to say nothing of jarring the fingers of the operator and the damage to his temper.

The drills should now be about 18 inches long, 6 or 7 inches of one end being octagon, 2½ ins. taper and 9 or 10 ins. ½ in. in diameter, and round. After finishing as many drills in this manner as it is desired to make, allow them to cool slowly; under no pretence whatever quench them in water or let them lie upon an iron surface while cooling. It is best to throw them upon the coal and dust on top of the forge, or, if it is desired, stick them into dry dirt and ashes in any convenient place.

To sharpen the drill, hammer one inch on one end of the drill to a square section; then flatten out to a flat point, so that the bevel will be about 1½ inches long. Hammer the edges frequently, so that the drill will not spread in width. Upset the end of the drill occasionally so that it asumes and retains a slight diamond shape when drawn down to 1 16 of an inch in thickness at the extreme point; the corners of the drill will be about 1/12 of an inch in thickness. Revolve the drill upon the anvil so that one side of the diamond-shaped end lies true with the outer face of the anvil. With light, true blows thin this side of the diamond point down to 1/16 of an inch, allowing the drill to spread sidewise at the same time. Treat the other side of the drill in the same manner, and after a little truing up of the edges of the drill, it has assumed a correct shape and is ready for hardening.

Heat about two inches of the drill to a dull red; for some steel the cherry red will be sufficient, but other varieties require a little more heat. Heat slowly so that the heat is uniform and the color alike all over the heated portion. Lower the drill slowly into a pail of cold water, the point first, and do not hold the drill still for an instant while it is in water. If two inches of the end have been heated, lower the drill into the water about one inch, passing it down slowly and steadily as stated; the end of the drill will then be as hard as "fire and water can make it."

Remove from the water immediately after it has reached the desired depth and polish by rubbing upon a piece of board, on top of which a little sand or dirt has been sprinkled. The polishing process is merely to allow the color to be seen as the temper runs down from the heated portion of the drill. During the drawing process, skill and judgement are the only guides to obtaining a drill that is just hard enough to do the work, and not hard enough to break. The color necessarily varies with different qualities of steel. The steel that will not bear heating harder than a cherry red must have a temper drawn to a purple or blue color. Steel that stands a higher working temperature will stand a straw color for temper and perhaps even lighter.

The instant that the red color is noted the drill must again be plunged into the water.

PORTRAIT OF THE LATE W. G. STORM, R. C. A.

BANK OF MONTREAL, WEST END BRANCH, MONTREAL. TAYLOR & GORDON, ARCHITECTS, MONTREAL.

PROPOSED HOUSE, VANCOUVER, B. C., FOR MR. O. G. EVAN THOMAS, ESQ.— FRIPP AND WILLS, ARCHITECTS, VANCOUVER.

This picturesque country house is to be a frame-built structure, covered with shingles, and to have leaded light windows in large square. The roof timbers will be stained dark to match teak; the mantelpieces, and internal finish generally, to be made of teak, imported from the east and made there. The cost will be about six thousand dollars; but as houses are usually finished in Vancouver, the cost would, perhaps, be only some five thousand dollars, which seems very cheap for a house of this size.

This is one of the cases in which the plan arrangement is very much due to the client, the particular arrangement here shown having been laid out by Mr. Thomas's own suggestion in every particular. The large galleried hall, with its encircling gallery and lookout recess over the porch, will be a very pleasant feature if in bad weather it is kept warm and free from draught.

The description and illustration are reproduced from a recent number of the *British Architect*.

PRESBYTERIAN CHURCH COMPETITION—DESIGN BY "JOHN KNOX." (MR. A. E. WELLS), TORONTO, AWARDED FIRST POSITION.

The instructions to competitors for the class in which this design was submitted called for a country church to seat from 150 to 200 persons, with one room to be used as vestry and library; and the building to be heated with stoves.

This is a design for a wooden building with a stone base to the height of the window sills. Externally the walls and roof are intended to be covered with shingles and left to be stained by rain and weather. Internally it is purposed to treat the roof entirely in wood and the walls to the height of the window sills with a moulded wood dado; the remainder of the wall space to be plastered, the brown plaster to be straightened and the walls finished without the usual white coat. All internal woodwork not exposed to handling is intended to be oiled merely, and left to turn richer in color with age. It is estimated that this design would cost in execution from $2,500 to $3,000.

TORONTO BUILDERS' EXCHANGE.

On July 27th, the members of the Exchange, together with their friends, about 325 in all, took a trip to Olcott, N. Y., on the "Carmona," leaving Geddes' wharf at 8 a. m., and returning at 9:30 p. m. The weather was all that could be wished for. The excursionists, for the most part, appeared to better appreciate quiet discussion in the shady park, than amusement requiring much exertion, as the temperature was "away up." The return passage was made very pleasant by the cool breezes of the lake and by a musical entertainment under the able direction of Mr. J. Lester Nicholls.

The excursion is the first venture of the kind since the Exchange was organized, and the success of the experiment will probably induce the members to make it an annual "institution."

PERSONAL.

F. M. Rattenbury, architect, has opened an office in Vancouver.

Mr. Copping, Building Inspector, Toronto, recently received serious injury by falling from a street car.

Mr. Louis Coste has received the appointment of Chief Engineer of the Public Works Department of Canada.

The Toronto Plate Glass Importing Co., their employees and friends, enjoyed their annual excursion and picnic on the 6th inst. Their objective point this year was Galt, Ont.

Mr. Arthur E. Wells, Secretary of the Toronto Architectural Sketch Club, a young man of marked ability, is about to leave Toronto to take up his residence and pursue the study of his profession in New York. The best wishes of many friends for a prosperous future will accompany him.

A PLEA FOR PERFECTION IN BRICKWORK.

The perfect in building construction may be said to be reached when there is obtained a maximum of strength and durability at a minimum cost. To design a roof, a floor or a wall that shall be strong enough to carry the load to be placed upon it, and strong enough to resist the thrusts that may be put upon it, is simple enough; the problem is to design in such a way that the portion of the structure is exactly strong enough and no stronger than is required; in other words, that there is no waste.

Having these facts in mind, it is easy to understand why there is so great a difference between carpentry in the United States and in England, and some parts of Europe. In this country timber is cheap and labor comparatively dear, while in England the reverse is true, and labor is cheap and timber comparatively dear. Adding the expense of freight to American timber used there, the cost will be somewhat more, while labor costs in round figures only about one half of what it does here. These facts affect and regulate construction to a very great extent, and what would at first appear to an English carpenter faulty and wasteful construction, is simply the result of a desire to save time; in other words, material is sacrificed for saving of labor.

These facts are equally true as far as brick construction is concerned, and it it is doubtless due simply and only to the desire to save time that the imperfect, faulty, and altogether wasteful method of laying bricks in "running" or "American bond" has come into general practice. It has been suggested in these columns that the fact of face bricks being of a different size to those on the interior of the wall is responsible for the use of the bond, but the writer thinks that this does not by any means explain it all, although it may to some extent. There is no reason in the world why the back of a wall, whatever the sizes of faces and back may be, should be laid in running bond.

Now, in the construction of buildings as in other things, it is often profitable to closely and critically examine the methods followed elsewhere to ascertain whether they may not be adopted with advantage here. It is certain that no part of a building deserves perfection in construction, so to speak, so well as does brickwork, and this for the simple reason that no portion is less liable to decay. The best bricks, and this litterally means bricks of the highest quality, are exceeded in durability by no known material used in the construction of buildings. Iron rusts; timber decays; stone perishes, and if it be limestone is destroyed quicker than timber; but good brick resists the action of atmosphere, fire and water, and lasts for ages. The very strength and durability of brick have been the cause of poor brickwork, paradoxical though it may seem.

To construct a brick wall that shall be as strong as possible from the material at hand would appear to be eminently desirable, but a wall erected in running bond falls short of this.

This is not difficult to understand. The system of construction violates the most important principle of bonding which is, that no two vertical joints shall come over one another. Suppose that there were no consideration of appearance, why not pile the bricks up one upon the other irrespective of bonding? "Oh," the bricklayers will tell you, "we must get bond,"—he must interlap the bricks to get bond,—to get strength on the face of the wall. Why not get bond through the breadth of the wall as well? That there is a necessity for it will not be denied, for the whole weight of the building rests on the inside portion of the wall, and it is of the utmost importance to distribute this weight through the thickness.

That which comes nearest to a perfect wall is that system of construction knows as "English bond," in which the bricks are all laid headers, excepting at the face, in alternate courses, when they are laid stretchers. This system of construction produces a wall in which the fundamental principle of bond is closely adhered to, and it will be found that, when it is faithfully carried out, no two mortar joints, in any part, come over one another. Flemish bond, although less perfect from a constructional point of view, is very considerably stronger than running or American bond, while its appearance is generally acknowledged to be very much superior.

Now, while the strength of a wall erected in English bond is very considerably stronger than one built in running bond, it is a fact to which due regard must be paid that the latter effects a saving of time. But while it is true that running bond can be built somewhat quicker than English, the writer claims that the advantage gained in this respect is so small as to be altogether inadequate to compensate for the great decrease in strength. It may be added, that, when he has urged architects to specify English and Flemish bond, he has been told that builders would refuse to construct them without an exorbitant increase of cost, being actually bound by the journeymen bricklayers to lay only the system of bonding they have been used to. This idea is doubtless exaggerated because no small porportion of working bricklayers are foreigners and are well acquainted with the correct methods of laying English and Flemish bonds.

But whatever bond is used in the construction of walls, there are certain other points of importance that are only too frequently overlooked. The first of these that may be mentioned is "damp courses." In Europe the use of damp courses is rendered compulsory by the building laws in most large cities. A damp course, if constructed of proper materials, is absolutely effectual in preventing the rising of moisture by capillary attraction from the earth and the consequent dampness of the walls.

"How to cure damp walls," is a question that is propounded to the architects' and builders' journals very frequently by house owners and others who are suffering from this trouble, and who not infrequently state that they have tried the application of various kinds of paint to the surface of the walls with the only result of driving the moisture higher up the wall. In such cases an effectual remedy may be found in inserting damp courses throughout the wall, underpinning it as may be necessary, although, of course, the damp course should have been inserted when the wall was built.

A good damp course may be constructed of three layers of common roofing slates, laid in cement with the joints lapping, the edges of the slates projecting to about an inch or so beyond the side of the wall. The damp-course, of whatever kind it is, should be put in just above the ground line. A layer of Portland cement (that is, cement mixed with water without the addition of sand) spread over the surface of the wall, to the thickness of three fourths of an inch, makes a very effective damp course, as does also a layer of bituminous asphalt laid in the same way. Sheet lead is also used and possesses the advantage of yielding somewhat to the inequalities of the brick or stone, and by that means distributing the weight more equally over the area. Damp courses may be constructed of other materials: in fact anything that is absolutely impervious to moisture and may be applied to the thickness of the walls is suitable.

While the fact that damp courses are very little used can but occasion surprise to those who have had an opportunity of having seen them in constant use, the fact that hollow or cavity walls are so used is even more surprising. Brick buildings, when standing in isolated positions may always be erected with advantage with a cavity wall, because any moisture passing through the outer casing cannot find its way into the interior of the building. Cavity walls are constructed of what are practically two walls, built side by side parallel and at a distance apart of about two inches, the two casings being closely tied together either by brick or by iron ties specially made for the purpose inserted in every fourth course at a distance apart of about two feet six inches. The wall, from the foundation up to the ground line, is built solid, and on the top is formed a damp course upon which two cavities are built. The portion between the cavities thus forms a gutter and is constructed with a fall so as to allow any water that may find its way in to run down the drains with which the cavity is connected. Sheet lead or sheet zinc is inserted over all door and window openings. In case of brick-and-a-half walls, which consists of one brick wall and a half brick wall, connected as described, it will be a subject of consideration as to whether a thicker or thinner casing should go on the outside. As a rule a thicker is preferred on the exterior, as it offers the greater resistance to the moisture finding its way in; but in any case it is well to observe that the floor and roofing timbers should always rest on the thicker casing.

One of the most important advantages of hollow cavity walls is the important influence it has on the temperature of the house. The two inch space of air in the centre of the wall acts as a sort of a non-conductor, and the variations in the atmosphere are felt to anything like so great a degree as they are when the walls are built solid. In other words, houses built with these walls are warmer in winter and cooler in summer.

Another point of construction that may be referred to is the hoop iron bond; this costs so little and adds so much to the strength of the brickwork that it is a difficult to understand why its use has not become general. Hoop iron used for this purpose is about an eighth of an inch thick, and one and a half inches broad. It is laid in every fourth course right along the wall, one row of hoop iron being inserted for each half brick in the wall's thickness; the hoop iron is riveted at the angles. In order to prevent the iron from rusting, it is covered with tar of zinc. The edges are generally jagged with the object of getting a better grip of the mortar, and the hoop iron holds the wall together and assists in distributing weight and is in every way desirable. Its cost is little, and the work it does great.

The writer, in preparing the above, has only referred to one or two of the more important directions in which it would appear that an improvement might be made in the construction of brickwork. Architects and builders have now better facilities for producing perfect brickwork than they ever had in the history of the world; and they should make it a matter of pride to see that the most perfect building material approaches as nearly as possible to perfection in construction.—Arthur Seymour Jennings in *The Brick Builder*.

THE ARCHITECT AND THE CONTRACTOR.

By Edward Hurst Brown.

"O wad some power the giftie gie us,
Tae see oorsel's as ithers see us."

It may be very well for the poet to write that way, but how many of us, I wonder, would feel highly flattered if we really knew what other folks think of us, down deep in their hearts. I have read with interest the reports of the various conventions of master painters as they have occurred from time to time, and while I have seen recorded there many words of self glorification and self satisfaction, as is perfectly natural—unfortunately most of the members seem so carried away with enthusiasm of the moment, that they forget there may be others who do not always look upon the performances of painters and decorators in general through the same rose tinted spectacles that these estimable gentlemen do themselves. Now I hope, my dear readers, if you have not become restive and sought some other article, before reading thus far, that you will bear with me patiently, even if I do say some few unpleasant things. Remember, it is not you I am talking about—it is the other fellow, that poor slouch who never read the *Painter's Magazine*, or the old timer who is so set in his old fogy notions that he never can believe that there is any other way to do a job than the way he learned some thirty or forty years ago. Of course you are too progressive not to fall in at once with an architect's notions, so you won't feel offended at what I may have to say. I have not failed to notice that you are all fond of having a little fling at the architects, not only in your conventions but in the columns of the magazines. Sly digs now and then or perhaps letters complaining of the manner in which these autocrats of the T square dictate to you, and insist that you shall do things as they want, and not as you would perhaps do otherwise. Now, is it not fair play that I, as an architect, may say a few words from the architect's point of view? Don't forget that this much abused personage occupies a very peculiar and delicate position in the erection of the building. The owner goes to him and regards him as a professional adviser, much the same as he consults a lawyer or a doctor. In this capacity he prepares the plans for the work in hand and writes the specifications for it. Here his advisory capacity ends and he becomes the agent of the owner, and, as such, proceeds to make contracts on behalf of the owner and see that they are properly carried out. But, as agent he has no authority whatever to alter in one jot or tittle the drawings or the specifications which he has prepared as the professional adviser. Moreover, he is legally responsible to the owner, in as great a degree as the contractor, for any deviations made by the mechanics employed upon the work. Although in his professional capacity he is responsible for any errors he may make in plans or specifications involving either questions of stability or adaptability to the purposes intended by the owner, as set forth in the instructions given to the architect, still, as agent he has neither power nor authority to modify these plans or specifications in the slightest degree, nor to allow any variation from them without the consent of the owner. When the building is

completed it is the architect who has to bear the blame and shoulder the responsibility for all defects in either workmanship, material, or faulty or inartistic designing. The contractor, more especially the sub-contractor, is rarely thought of by the owner. He is supposed in his work merely to carry out the instructions given to him by the architect.

I have entered into this rather full account of the relations existing between the owner and the architect because I think, as a rule, they are very little understood. Most mechanics regard the architect, in his capacity as supervisor of the work, as having absolute authority to order or permit changes or extra work at his own sweet will without regard to the owner, who stands back of the architect and is the real party to the contract. Hence, they feel little or no compunction about changing the methods or materials designated by the specifications if, in their opinion a better job may be obtained, or one which they believe would be more creditable to them or more workmanlike, relying on the good nature of the architect to permit such changes, if detected by him. As a rule, he is not consulted beforehand. Now, this may be, and frequently is, done with the most honest intentions in the world. The work substituted for that specified may be just as strong, just as durable, and perhaps may be even better, and may cost the contractor more money. But (and this "but" is a very strong one), the contract is not carried out, and though the work may be better, though both architect and contractor may be able to prove it so, the owner can, if he wishes (and sometimes he does wish to do it) bring suit against the architect and recover heavy damages, sometimes many times in excess of the fee charged for professional services. As a case in point I know of a firm of architects who were compelled to spend three times the fee they received on a certain building in order to pay their lawyer for defending them in a suit brought by an owner under circumstances precisely similar. Fortunately, they were enabled to prove to the satisfaction of the jury that the work did not differ materially from that specified, or they would have been mulcted in heavy damages as well. Hence, the architect's position is by no means a bed of roses, and it seems to me to be a little unfair in the mechanic who is called upon to do the work in accordance with certain definite specifications, to set himself up as superior to the contract, to feel that the architect is not treating him fairly in setting forth in definite terms the manner of doing the work, and to complain because the architect particularly calls for certain specified materials. You may say that you, having devoted your lives to a certain trade, ought to know more about it than an architect who has never handled a brush or mixed a pot of paint in his life. Undoubtedly you do about the practical application of the principles which govern your work, though you may not know as much of those principles as the architect whose knowledge of the subject you are trying to treat with contempt.

Doubtless you may come across foolish or carelessly drawn specifications. There are careless, young, or inexperienced architects, just as there are careless, young and inexperienced lawyers or doctors. But remember it is the architect who is responsible for the carelessly drawn specifications, not you. If you are afraid that doing a job in the manner specified will injure your reputation as a painter, you are privileged to refuse to estimate upon the work; or, having done so, you need not sign a contract for it if, in your judgment, the specification calls upon you to do a poor, unworkmanlike job. It is your privilege before entering into a contract to object to any of its terms, and to insist or request, as the case may be, that it be modified before you sign it; but having once signed a contract to do work under certain specifications, whether this contract be a direct one with the owner, or an indirect one through a builder, you are bound both morally and legally to fulfill that contract to the letter, and any variation therefrom without the consent of the other party is dishonest, even though your variation may make what you deem to be an improvement in the manner of executing the work. Now, these are plain words, but when you come to look upon a contract in its full legal aspect, and to view it from every side of the question, you cannot fail to see I am right.

You may think an architect should not specify any particular material to be used, but I say an architect is bound to use his professional knowledge to discover what he believes to be the best material and mode of executing the work to suit the particular case on hand, and to further the interests of his client; not necessarily to make the best possible job in every case, but to make the job best adapted to that special piece of work. If the architect considers his client's interests are best served by the use of a certain kind of varnish, or a certain make of ready mixed paint, he is bound, in duty to his employer, to specify accordingly, and the painter who accepts the contract under those particular conditions is equally bound to see that these materials are used upon the job. I know of one case where, owing to certain personal and business relations existing between the owner of several houses and a certain firm manufacturing a special brand of ready mixed paints, the architect received definite instructions to specify that particular brand. The painter, knowing nothing of the circumstances, and not having much confidence in the paint in question, mixed his own colors, to match in shade the numbers specified by the architect. The consequence was that the architect, having failed to require the compliance with the contract, was held responsible by the owner, though fortunately a law suit was avoided, but the paint manufacturers withdrew a very important business relationship from the owner of the houses. Can any possible process of reasoning justify that painter for having departed from the strict letter of the specifications?

Then again the architect is looked to for the artistic effect of the building, and may specify that the work shall be done in a particular manner, in order to obtain a result which he knows will please him, and his client as well, although it may look rough and unfinished to the mechanic who has been trained up to do the work in a different manner. I know in one case I wished to obtain a certain effect on oak wood, and specified that the work was to have a light coat of paint, which was to be wiped off with a cloth, then followed by two coats of varnish rubbed to a dull gloss. When the work was finished I expected to see the texture of the wood plainly. Judge of my horror when I found that the painter, thinking I had made a mistake in myspecification, and had neglected to specify any filler, without consulting me in any way, filled the oak with paste filler before applying the paint. The whole scheme of the work was changed, and the effect I was trying to obtain was lost. Moreover, a special hanging, which was being made to harmonize with the rough woodwork, seemed strangely out of place with the smooth surfaced wood. At another time I had occasion to paint a certain studio wall, and mixing some Indian red and raw sienna to get just the tint I wanted, gave a light wash of water color over the paper, in such a manner that the brownish gray background showed through the color. I instructed the painter that this was the effect I wanted on the wall, which was to be done in water color. When I next visited the room I was horrified to find a solid coat of color on the walls; the shade was matched, it was true, but the effect was totally different from my instructions. Fortunately, in this case, I could set the men to work with sponges to wash off the superfluous color, and get very near the effect originally intended.

Now don't for a moment think that all mistakes and all disregard to the terms of the specifications are confined to the painters. Other mechanics are just as apt to err, or to set themselves up as superior to the architect. But I do want you to bear in mind that the architect is the responsible head, and that it is better in most cases to follow his instructions than to think your way is best. Don't think that every time he specifies a particular brand of varnish or color, or calls for a special make of white lead, that he is actuated by underhand bribes from the manufacturer. I can tell you, and I know well what I am talking about, that not one reputable architect in a hundred will accept a bribe or an illicit commission as an inducement to specify particular makes of goods, and the manufacturers who attempt to offer such commission usually get sadly left. I do not speak of the self-styled builder architects of small country towns. I don't know what they may do, though I hope they are honest; but I refer to the educated, conscientious, painstaking members of the profession whose practice is in the great cities, and who make up the membership of the American Institute of Architects. If you wish to bring them into sympathy with you, don't sulk in corners, call names, and say you won't play, like silly boys, but get them interested in your associations and your conventions, and you will soon bring about a better relationship between your trade and the architects of the country.—*Painters' Magazine.*

THE LATE W. G. STORM, R. C. A.

THE removal by death on the 1st inst. of the subject of this sketch, has taken from our midst one who has filled a very important place in the architectural work of not only this city of Toronto, but of the province of Ontario, during the last forty years.

He was of English lineage, born at Burton-upon-Strathar, Lincolnshire, England, October 29th, 1826, and came to Canada with his parents in 1830. They left Hull, England, in a sailing vessel on the 29th May, landing in Little York, (now Toronto), in August of the same year. He has therefore spent 62 years of his life in Toronto.

As a youth he was apprenticed for five years to his father, who carried on an extensive business as a builder and contractor, and he early developed a taste for architecture. When 18 years old he was articled to the late Mr. William Thomas, an architect of great taste and skill in Toronto, in whose office he continued for some years.

In 1848 he became associated with the late F. W. Cumberland, Esq., as assistant. In 1849 old St. James cathedral was burned, which was the second destroyed by fire on the same site. Plans for a new church were advertised for, premiums offered, and the first prize was awarded to the plans prepared, it is said, by Mr. Storm, in Mr. Cumberland's office. About the close of 1850 a partnership was formed between Messrs. Cumberland and Storm, and soon they became the leading firm in both city and province. St. James cathedral, the Normal School and the Mechanics Institute buildings were among their earlier work in this city, and among the counties of the province they had to do with many municipal buildings. The erection of the new University buildings in Queen's Park from an important era in the architecture of the city, and with them Mr. Storm was associated from the first in the development of the plans and details and the construction and completion of the buildings. Thoroughness was an important feature in Mr. Storm's work, and owing to this and his practical knowledge gained by him in the workshops of his youth, the Toronto University buildings presented about as perfect a piece of building as could be found on the continent.

The centre building of Osgoode Hall followed close on the completion of the University, and with this Messrs. Cumberland & Storm had to do. Opened in 1860 by the Prince of Wales, it was referred to as the finest law library building in the world. St. James' Cemetery Chapel, St. Andrew's Church, corner of King and Simcoe streets, among others, were his work, and finally the handsome and commodious pile which his eyes just failed to see completed in Queen's Park, the Victoria Methodist College buildings.

At the organization of the Ontario Association of Architects in March, 1889, Mr. Storm was chosen President, which position he held until the second annual convention of the Association which took place in February of the present year. This position was one of peculiar pride to him; as well as to his associates to have him there. He was indeed an ornament to his profession.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS' EXAMINATIONS.

The following are the examination papers used in the recent examinations of the above Association:

Arithmetic.

1. Add 52 multiplied by 321 to 87 multiplied by 139, divide by 12 multiplied by 7, and subtract 13 multiplied by 8.
2. Divide 19 multiplied by 158 by 44 multiplied by 7.
3. The following deposits are made in a bank:
   $10.00 at 4% for 1 year.
   $16.00 at 5% for 3 years.
   $26.00 at 6% for 8 months.
   What is the amount of interest on deposit?
4. Bricks cost at the yard $7.00 per M and $1.00 for cartage. What will be the cost of 142,700 bricks at the building.
5. Find the number of rolls of paper required to paper the walls of a room 21 feet square and 10.6 high from top of skirting to ceiling, a roll of paper being 8 yards long by 18 inches wide.

Algebra.

1. Reduce to their simplest forms:
   (*a*). $(a-x)-(2x-a)-(2-2a)+(3-2x)-(1-x)$.
   (*b*). $a^2-(b^2-c^2)-\frac{1}{2}b^2-(c^2-a^2)\frac{1}{2}+\frac{1}{4}c^2-(b^2-a)\frac{1}{2}+3(b^2-c^2)$.
   (*c*). $1-\frac{1}{2}\,1-(1-4x)\frac{1}{2}+2x-(3-5x)\frac{1}{2}-\frac{1}{2}\,2-(-4+5x)\frac{1}{2}$
2. Multiply
   $x^2+2xy+2y^2$ by $x^2-2xy+y^2$.
   $x-1$ by $x+1$ and x^2+1.
   $a+b+c+d$ by $b+c-d-a$.
3. Simplify $\dfrac{2(x^2-\frac{1}{4})+\frac{1}{2}}{2x+1}$.
4. Reduce $\dfrac{x^3+3x^2-4}{x^3-1}$ to its lowest terms.
5. Solve the equations:
   (1). $2x-\frac{1}{3}=75\,(3-2x)+\frac{1}{2}x$.
   (2). $2.7x+\frac{1}{6}\,(x-1)=x-4$.
   (3). $\frac{1}{6}x-1\frac{2}{3}=83\,5+2(3\,5+2(3\,5x-1)-(x+8)$.

Mensuration.

1. A trapezoidal field has two parallel sides whose length are 8200 yds. and 6190 yds. respectively. The perpendicular distance between the sides is 220 yds. The rental of the field is $750.00 per annum, what is the rent per acre of 4840 square yards?
2. The height of a precipice standing 20 feet back from the side of a river is 112 feet and a line 200 feet long will reach from the top of it to the opposite bank, find the width of the river.
3. A building 210 feet long, 64 feet wide has a slate pitched roof 32 feet high measured perpendicularly hipped at a similar angle to sides, at both ends. How many squares of slating of 100 sup. ft. will there be in the roof?
4. A boundary wall is 940 feet long, 10 feet 6 inches high and 2 feet 4 inches thick, how many cube yards of stone will the wall contain?
5. A gallon of water contains 277.2 cub. inches and weighs 10 lbs. avoirdupois, find the weight of 3 cubic feet of water in ounces.

Euclid.

1. Any two sides of a triangle are together greater than the third side.
2. If a straight line falling on two other straight lines make the alternate angles equal to one another, the two straight lines shall be parallel to one another.
3. Parallelograms upon equal bases and between the same parallels, are equal to one another.
4. Divide a given straight line into 2 parts so that the rectangle contained by the whole and one of the parts may be equal to the square of the other part.
5. If a straight line be divided into any two parts, the rectangle contained by the whole and one of the parts is equal to the rectangle contained by the two parts together with the square on the aforesaid part.

Besides the foregoing there was a composition on a subject given by the examiners. Also freehand and linear drawing from copy.

A curious suit has been entered by the Queen of England in the New York courts to recover a cargo of asphalt recently brought from the island of Trinidad, and sold to the Standard Asphalt Company of New York. It seems that the island of Trinidad is the property of the British Crown. The principal source of asphalt in the island is the celebrated Pitch Lake, which is practically a mass of asphalt, or rather, bituman. This is collected by a simple process of driving carts upon the surface of the lake, which is solid enough to support them, and shovelling the material into them; and the price, on the island, of the asphalt so collected is about a dollar and a half a ton. The lake is entirely Crown property, but there are secondary deposits of asphalt in other parts of the island, which are least, or otherwise conceded, to private parties. According to the claim of the council for the Crown, the deposits of asphalt under private control are nearly or quite exhausted, and their proprietors have taken to replenishing their supplies of the material by poaching on the Queen's property. It seems that this reprehensible practice has become so general of late that the Crown officers detain, where they can, all vessels leaving the island with cargoes of asphalt until it is ascertained whether any of the asphalt was stolen from the Queen or not; but it is alleged that, in the present case, the vessel succeeded in escaping without being searched. On the other hand, the respondents assert that, as the Crown imposes an export duty of a dollar and a half a ton on all asphalt taken from the island, the Queen has already received the full value of the cargo, and that they believe the suit to be merely a contrivance to annoy them, devised by a rival asphalt company, which has made an agreement with the Crown officers, not to take asphalt from Crown lands.—*American Architect.*

completed it is the architect who has to bear the blame and shoulder the responsibility for all defects in either workmanship, material, or faulty or inartistic designing. The contractor, more especially the sub-contractor, is rarely thought of by the owner. He is supposed in his work merely to carry out the instructions given to him by the architect.

I have entered into this rather full account of the relations existing between the owner and the architect because I think, as a rule, they are very little understood. Most mechanics regard the architect, in his capacity as supervisor of the work, as having absolute authority to order or permit changes or extra work at his own sweet will without regard to the owner, who stands back of the architect and is the real party to the contract. Hence, they feel little or no compunction about changing the methods or materials designated by the specifications if, in their opinion a better job may be obtained, or one which they believe would be more creditable to them or more workmanlike, relying on the good nature of the architect to permit such changes, if detected by him. As a rule, he is not consulted beforehand. Now, this may be, and frequently is, done with the most honest intentions in the world. The work substituted for that specified may be just as strong, just as durable, and perhaps may be even better, and may cost the contractor more money. But (and this "but" is a very strong one), the contract is not carried out, and though the work may be better, though both architect and contractor may be able to prove it so, the owner can, if he wishes (and sometimes he does wish to do it) bring suit against the architect and recover heavy damages, sometimes many times in excess of the fee charged for professional services. As a case in point I know of a firm of architects who were compelled to spend three times the fee they received on a certain building in order to pay their lawyer for defending them in a suit brought by an owner under circumstances precisely similar. Fortunately, they were enabled to prove to the satisfaction of the jury that the work did not differ materially from that specified, or they would have been mulcted in heavy damages as well. Hence, the architect's position is by no means a bed of roses, and it seems to me to be a little unfair in the mechanic who is called upon to do the work in accordance with certain definite specifications, to set himself up as superior to the contract, to feel that the architect is not treating him fairly in setting forth in definite terms the manner of doing the work, and to complain because the architect particularly calls for certain specified materials. You may say that you, having devoted your lives to a certain trade, ought to know more about it than an architect who has never handled a brush or mixed a pot of paint in his life. Undoubtedly you do about the practical application of the principles which govern your work, though you may not know as much of those principles as the architect whose knowledge of the subject you are trying to treat with contempt.

Doubtless you may come across foolish or carelessly drawn specifications. There are careless, young, or inexperienced architects, just as there are careless, young and inexperienced lawyers or doctors. But remember it is the architect who is responsible for the carelessly drawn specifications, not you. If you are afraid that doing a job in the manner specified will injure your reputation as a painter, you are privileged to refuse to estimate upon the work; or, having done so, you need not sign a contract for it if, in your judgment, the specification calls upon you to do a poor, unworkmanlike job. It is your privilege before entering into a contract to object to any of its terms, and to insist or request, as the case may be, that it be modified before you sign it; but having once signed a contract to do work under certain specifications, whether this contract be a direct one with the owner, or an indirect one through a builder, you are bound both morally and legally to fulfill that contract to the letter, and any variation therefrom without the consent of the other party is dishonest, even though your variation may make what you deem to be an improvement in the manner of executing the work. Now, these are plain words, but when you come to look upon a contract in its full legal aspect, and to view it from every side of the question, you cannot fail to see I am right.

You may think an architect should not specify any particular material to be used, but I say an architect is bound to use his professional knowledge to discover what he believes to be the best material and mode of executing the work to suit the particular case on hand, and to further the interests of his client; not necessarily to make the best possible job in every case, but to make the job best adapted to that special piece of work. If the architect considers his client's interests are best served by the use of a certain kind of varnish, or a certain make of ready mixed paint, he is bound, in duty to his employer, to specify accordingly, and the painter who accepts the contract under those particular conditions is equally bound to see that these materials are used upon the job. I know of one case where, owing to certain personal and business relations existing between the owner of several houses and a certain firm manufacturing a special brand of ready mixed paints, the architect received definite instructions to specify that particular brand. The painter, knowing nothing of the circumstances, and not having much confidence in the paint in question, mixed his own colors, to match in shade the numbers specified by the architect. The consequence was that the architect, having failed to require the compliance with the contract, was held responsible by the owner, though fortunately a law suit was avoided, but the paint manufacturers withdrew a very important business relationship from the owner of the houses. Can any possible process of reasoning justify that painter for having departed from the strict letter of the specifications?

Then again the architect is looked to for the artistic effect of the building, and may specify that the work shall be done in a particular manner, in order to obtain a result which he knows will please him, and his client as well, although it may look rough and unfinished to the mechanic who has been trained up to do the work in a different manner. I know in one case I wished to obtain a certain effect on oak wood, and specified that the work was to have a light coat of paint, which was to be wiped off with a cloth, then followed by two coats of varnish rubbed to a dull gloss. When the work was finished I expected to see the texture of the wood plainly. Judge of my horror when I found that the painter, thinking I had made a mistake in myspecification, and had neglected to specify any filler, without consulting me in any way, filled the oak with paste filler before applying the paint. The whole scheme of the work was changed, and the effect I was trying to obtain was lost. Moreover, a special hanging, which was being made to harmonize with the rough woodwork, seemed strangely out of place with the smooth surfaced wood. At another time I had occasion to paint a certain studio wall, and mixing some Indian red and raw sienna to get just the tint I wanted, gave a light wash of water color over the paper, in such a manner that the brownish gray background showed through the color. I instructed the painter that this was the effect I wanted on the wall, which was to be done in water color. When I next visited the room I was horrified to find a solid coat of color on the walls; the shade was matched, it was true, but the effect was totally different from my instructions. Fortunately, in this case, I could set the men to work with sponges to wash off the superfluous color, and get very near the effect originally intended.

Now don't for a moment think that all mistakes and all disregard to the terms of the specifications are confined to the painters. Other mechanics are just as apt to err, or to set themselves up as superior to the architect. But I do want you to bear in mind that the architect is the responsible head, and that it is better in most cases to follow his instructions than to think your way is best. Don't think that every time he specifies a particular brand of varnish or color, or calls for a special make of white lead, that he is actuated by underhand bribes from the manufacturer. I can tell you, and I know well what I am talking about, that not one reputable architect in a hundred will accept a bribe or an illicit commission as an inducement to specify particular makes of goods, and the manufacturers who attempt to offer such commission usually get sadly left. I do not speak of the self-styled builder architects of small country towns. I don't know what they may do, though I hope they are honest; but I refer to the educated, conscientious, painstaking members of the profession whose practice is in the great cities, and who make up the membership of the American Institute of Architects. If you wish to bring them into sympathy with you, don't sulk in corners, call names, and say you won't play, like silly boys, but get them interested in your associations and your conventions, and you will soon bring about a better relationship between your trade and the architects of the country.—*Painters' Magazine.*

THE LATE W. G. STORM, R. C. A.

THE removal by death on the 1st inst. of the subject of this sketch, has taken from our midst one who has filled a very important place in the architectural work of not only this city of Toronto, but of the province of Ontario, during the last forty years.

He was of English lineage, born at Burton-upon-Strathar, Lincolnshire, England, October 29th, 1826, and came to Canada with his parents in 1830. They left Hull, England, in a sailing vessel on the 29th May, landing in Little York, (now Toronto), in August of the same year. He has therefore spent 62 years of his life in Toronto.

As a youth he was apprenticed for five years to his father, who carried on an extensive business as a builder and contractor, and he early developed a taste for architecture. When 18 years old he was articled to the late Mr. William Thomas, an architect of great taste and skill in Toronto, in whose office he continued for some years.

In 1848 he became associated with the late F. W. Cumberland, Esq., as assistant. In 1849 old St. James cathedral was burned, which was the second destroyed by fire on the same site. Plans for a new church were advertised for, premiums offered, and the first prize was awarded to the plans prepared, it is said, by Mr. Storm, in Mr. Cumberland's office. About the close of 1850 a partnership was formed between Messrs. Cumberland and Storm, and soon they became the leading firm in both city and province. St. James cathedral, the Normal School and the Mechanics Institute buildings were among their earlier work in this city, and among the counties of the province they had to do with many municipal buildings. The erection of the new University buildings in Queen's Park from an important era in the architecture of the city, and with them Mr. Storm was associated from the first in the development of the plans and details and the construction and completion of the buildings. Thoroughness was an important feature in Mr. Storm's work, and owing to this and his practical knowledge gained by him in the workshops of his youth, the Toronto University buildings presented about as perfect a piece of building as could be found on the continent.

The centre building of Osgoode Hall followed close on the completion of the University, and with this Messrs. Cumberland & Storm had to do. Opened in 1860 by the Prince of Wales, it was referred to as the finest law library building in the world. At the organization of the Ontario Association of Architects in March, 1889, Mr. Storm was chosen President, which position he held until the second annual convention of the Association which took place in February of the present year. This position was one of peculiar pride to him; as well as to his associates to have him there. He was indeed an ornament to his profession.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS' EXAMINATIONS.

The following are the examination papers used in the recent examinations of the above Association:

Arithmetic.

1. Add 52 multiplied by 321 to 87 multiplied by 139, divide by 12 multiplied by 7, and subtract 13 multiplied by 8.
2. Divide 19 multiplied by 158 by 44 multiplied by 7.
3. The following deposits are made in a bank:
   $10.00 at 4% for 1 year.
   $16.00 at 5% for 3 years.
   $26.00 at 6% for 8 months.
   What is the amount of interest on deposit?
4. Bricks cost at the yard $7.00 per M and $1.00 for cartage. What will be the cost of 142,700 bricks at the building.
5. Find the number of rolls of paper required to paper the walls of a room 21 feet square and 10.6 high from top of skirting to ceiling, a roll of paper being 8 yards long by 18 inches wide.

Algebra.

1. Reduce to their simplest forms:
   (*a*). $(a-x)-(2x-a)-(2-2a)+(3-2x)-(1-x)$.
   (*b*). $a^2-(b^2-c^2)-\frac{1}{2}b^2-(c^2-a^2)\frac{1}{2}+\frac{1}{3}c^2-(b^2-a^2)\frac{1}{3}+3(b^2-c^2)$.
   (*c*). $1-\frac{1}{2}\,1-(1-4x)\frac{1}{2}+2x-(3-5x)\frac{1}{2}-\frac{1}{2}\,2-(-4+5x)\frac{1}{2}$.
2. Multiply
   $x^2+2xy+2y^2$ by $x^2-2xy+y^2$.
   $x-1$ by $x+1$ and x^2+1.
   $a+b+c+d$ by $b+c-d-a$.
3. Simplify $\dfrac{2(x^2-\frac{1}{4})+\frac{1}{2}}{2x+1}$
4. Reduce $\dfrac{x^3+3x^2-4}{x^3-1}$ to its lowest terms.
5. Solve the equations:
   (1). $2x-\frac{1}{4}=75\ (3-2x)+\frac{1}{2}x$.
   (2). $2.7x+\frac{1}{6}\ (x-1)=x-4$.
   (3). $\frac{1}{6}x-1\frac{2}{3}=83\frac{1}{3}+2(3.5+2(3.5x-1)-(x+8)$.

Mensuration.

1. A trapezoidal field has two parallel sides whose length are 8200 yds. and 6190 yds. respectively. The perpendicular distance between the sides is 220 yds. The rental of the field is $750.00 per annum, what is the rent per acre of 4840 square yards?
2. The height of a precipice standing 20 feet back from the side of a river is 112 feet and a line 200 feet long will reach from the top of it to the opposite bank, find the width of the river.
3. A building 210 feet long, 64 feet wide has a slate pitched roof 32 feet high measured perpendicularly hipped at a similar angle to sides, at both ends. How many squares of slating of 100 sup. ft. will there be in the roof?
4. A boundary wall is 940 feet long, 10 feet 6 inches high and 2 feet 4 inches thick, how many cube yards of stone will the wall contain?
5. A gallon of water contains 277.2 cub. inches and weighs 10 lbs. avoirdupois, find the weight of 3 cubic feet of water in ounces.

Euclid.

1. Any two sides of a triangle are together greater than the third side.
2. If a straight line falling on two other straight lines make the alternate angles equal to one another, the two straight lines shall be parallel to one another.
3. Parallelograms upon equal bases and between the same parallels, are equal to one another.
4. Divide a given straight line into 2 parts so that the rectangle contained by the whole and one of the parts may be equal to the square of the other part.
5. If a straight line be divided into any two parts, the rectangle contained by the whole and one of the parts is equal to the rectangle contained by the two parts together with the square on the aforesaid part.

Besides the foregoing there was a composition on a subject given by the examiners. Also freehand and linear drawing from copy.

A curious suit has been entered by the Queen of England in the New York courts to recover a cargo of asphalt recently brought from the island of Trinidad, and sold to the Standard Asphalt Company of New York. It seems that the island of Trinidad is the property of the British Crown. The principal source of asphalt in the island is the celebrated Pitch Lake, which is practically a mass of asphalt, or rather, bituman. This is collected by a simple process of driving carts upon the surface of the lake, which is solid enough to support them, and shovelling the material into them; and the price, on the island, of the asphalt so collected is about a dollar and a half a ton. The lake is entirely Crown property, but there are secondary deposits of asphalt in other parts of the island, which are least, or otherwise conceded, to private parties. According to the claim of the council for the Crown, the deposits of asphalt under private control are nearly or quite exhausted, and their proprietors have taken to replenishing their supplies of the material by poaching on the Queen's property. It seems that this reprehensible practice has become so general of late that the Crown officers detain, where they can, all vessels leaving the island with cargoes of asphalt until it is ascertained whether any of the asphalt was stolen from the Queen or not; but it is alleged that, in the present case, the vessel succeeded in escaping without being searched. On the other hand, the respondents assert that, as the Crown imposes an export duty of a dollar and a half a ton on all asphalt taken from the island, the Queen has already received the full value of the cargo, and that they believe the suit to be merely a contrivance to annoy them, devised by a rival asphalt company, which has made an agreement with the Crown officers, not to take asphalt from Crown lands.—*American Architect.*

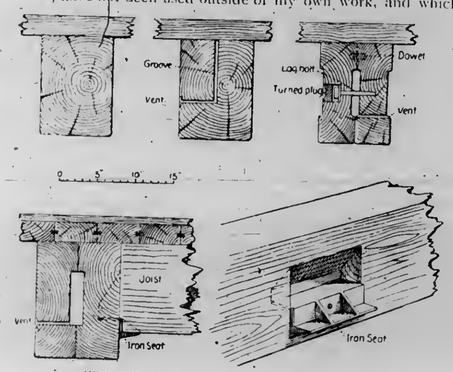
NEW METHODS IN HEAVY TIMBERING.

The following article on this subject from Mr. Frederic G. Corser, architect, Minneapolis, Minn., appears in a recent number of the *Engineering News*:

The great success of the building now much in vogue for warehouses and factories, known as the "mill construction," and the probable extension of some features of this system to other classes of buildings than those mentioned, has been productive of more or less study of the subject of timbering. If we except the efforts made within a comparatively short time to reform the timbering customary in these factories and storehouses, we must look in vain for recent examples of even tolerable timber-work. All the traditions to be acquired by the present generation of builders lie in the direction of rough, cheap work, intended to be concealed from view. No builder of this day thinks that the timbering of the ordinary building is a thing to be proud of under any circumstances. The carpenters of the day will look over the old works on the subject with rather more pity for the simplicity of the old builder, which led him to waste his time on the splendid framing shown, than of admiration for that framing.

Another factor in the decline of timber-work is the cheapness of sawing and dressing lumber in our time, which has increased the tendency to hide the actual construction by boxing or casing it in. When to this we add that the properties of timber used transversely are not generally well understood, we find sufficient causes for a decidedly low state of the art of timbering. However, with an amount of ingenuity and technical skill unknown to former times, seeking employment in every field, it were indeed a pity if the art of timbering were overlooked; and now that there are such good economical reasons for the use of heavy timbering, left in full view, we may look to see the objectionable features overcome.

The accompanying cuts give some things which, as far as I know, have not been used outside of my own work, and which



NEW METHODS IN HEAVY TIMBERING.

are submitted as in the right direction. The drying of large timbers being a slow process, proceeding from the outer and newer tree growth which shrinks most, to the inner and older wood which is more stable, we get under the ordinary conditions several unsightly cracks, due to the strains set up by this unequal drying. Aside from their unsightliness, these cracks are often of considerable damage to the timber from the standpoint of strength. The boring of posts from end to end has long been done, and when the holes thus made are of considerable size, and vented by transverse holes at top and bottom, the trouble is overcome to some extent: Were it practicable to bore the floor timbers in this way, the benefits would be even greater than to the posts, because in the timbers used transversely we could bore out a relatively large part of the centre without weakening them. However, boring requires special machinery, not to be found around saw-mills or planing-mills, and there are limitations to the length of the timbers that one can get bored. After trying for some years to get manufacturers of lumber to put in the necessary machinery for boring, I gave it up.

A deep groove may be worked in from the upper edge, a circular saw being specially set for the purpose. This method is open to the objection of destroying a few of the fibers opposed to the compressive strains, but it is even more efficient in reducing the tendency to crack than is the boring. The preservation from season-cracks would doubtless in some cases prevent a loss of strength that would offset the amount taken away by the grooves.

An old way of reducing the tendency to season-cracking consists in splitting the timber through the center with the saw, turning the outer sides inward, and bolting. This was a favorite prescription by Viollet le Duc. It puts the older and more permanent part of the tree-growth outward, and as this is less liable to shrink than the sappy newer growth, it not only relieves these seasoning strains by so much as would naturally follow from dividing the timber, but it also exposes the part of the timber which cracks least.

There are also other advantages in thus making up the timber in two parts, among which is the opportunity given to inspect the heart of the tree; this portion being, as is well known, subject to decay which does not manifest itself at the surface. Another advantage of using the timber of two parts is the fact that in the operations of the modern sawmill, larger timbers can in this way be sawn from a given diameter of logs. Still another gain to the building is to be found in the greater progress of the seasoning process in the interval between the cutting of the lumber and its final assembling in place in the building.

Not long since it occurred to me that possibly broad grooves or panels might be worked in the sides of the pieces thus proposed to be bolted together, the operation being done at the planing-mill at the times of dressing of lumber. Upon enquiry, I find that the planers in use at these mills for doing the bulk of their work may be easily modified to work these channels, and I have had estimates for doing it at a very low figure.

As grooves or panels of about the proportion shown in the cuts may be made without taking from the strength of the pieces when subjected to transverse strain, this form becomes desirable for several reasons. The seasoning of the timber prepared in this way would be accomplished in a fraction of the time required by a solid timber; the panelling would so reduce the pieces at the center as to remove the tendency to season-cracks; considerable weight would be saved in freighting and handling on the building; the interior could be dried while the under side of the timber, being practically solid, would resist fire well, and if the outer sides were also panelled, it would do much toward relieving the appearance of the timbers, by introducing lines that would in a measure take the attention from the unsightly features of common lumber. In fact, this treatment of timbers will go far toward making open timber-work desirable in other classes of buildings than factories and warehouses. Floors built on this principle are much to be desired in schools, for instance, where by their substitution for the common thin joist and concealed construction, and by the use of open-timber roofs of suitable detail, a practically fire-proof building may be obtained at less cost than one of the kindling-wood structures so nearly universal.

I am indebted to Mr. C. J. H. Woodbury for the suggestion that the small vent-holes be placed at a low enough level to drain the inside of any water that might get into the centre during or after building. For bolting the halves of the timber together, lag-screws are used as shown, because they would not become so loosened by the shrinkage of the wood as would the common bolts running clear through. A few dowels might be inserted with profit in the upper part of the girder liable to unequal loading, as the planking, being parallel with it, would not be of assistance in distributing the load over the two halves. The dowels, replacing fibres subject to compressive strains only, would not take from the strength of the beam.

The iron stirrup, so commonly used for the support of timbers meeting at right angles, as when heavy joints are carried at one or both ends by girders, is far from an ideal way of accomplishing the desired result. It is clumsy in appearance, if not actually so in manufacture; it usually gives a rather poor bearing for the joists, while the shrinkage of the joist eventually leaves the top of it considerably below the top of the girder. The iron seat shown in the cut is designed to overcome these faults in a degree.

As we approach the neutral axis of the timber in which the mortise is cut, we find the fibers less and less strained under a load, so that we may remove a part of the timber without weakening it, provided we have enough wood at this point to bear the small strains that the timber will be called on to withstand at the level of the mortise. If in this mortise we place a casting of the form shown, and tenon the joist to fit, we shall get a bearing of the joist much better than that given by the stirrup; the arrangement will be much less unsightly, and nearly all the old trouble of shrinking away from the common level at the top, which gives so much trouble where stirrups are used, will be overcome.

DECORATION AND FURNITURE

OLD CANDLESTICK.

DEVELOPMENTS IN DECORATION.

A well-known writer says: "Art moves in cycles of styles. At one time a separate style in blended form is resurrected; at other times we witness blended styles. New combinations of old styles may create a novelty with nothing new in principle—new only in arrangement, and with no great variety in details. We have few decorative forms that do not retain some element of a preceding period." To this, says *Furniture and Decoration*, we cannot dissent. Those of us who have given any attention to the origin and composition of style in decorative art will readily agree that in the present era there is little or no purity; although we may be compelled to call such by, or adopt, some classical name for our purpose, the intent is not to deceive, but the designer merely wishes to convey the idea that the scheme was not to faithfully decorate in exact reproduction of some period or era of time, but simply to avail himself of the advantages of that peculiar style, with such adaptations, in form and color, discarding here, appending there, modifying this, strengthening that, and reserving the right to make such changes as will best accord with the surroundings, improvements, temperament and culture of to-day.

We endeavour to be as classical as our knowledge and resources of material will permit. We all know that to consistently decorate in say the "Louis XV.," or "Japanese" style, if we at all succeed in obtaining the genuine article, we do so at a great outlay, and then we may venture the opinion that our stained glass, mantel, and fire-place will be very modern, and the exterior architecture will be composite "Romanesque."

Although we are utilizing all styles in our present decorations, the predominating ones have been adapted from the French period of the "Rococo," the different kings, Louis XIV., XV., XVI., and the Empire. The revival of these style shas chiefly been confined to interiors, while the "Cinque Cento," "Italian Renaissance," "Romanesque," "Early English," and "Elizabethan," in composite form with "Celtic" and "Byzantine," as well as the "Adams," are extensively employed both for interiors and exteriors. Modern inventiveness joins hands with ancient picturesqueness, and produces varying and unique results. This we see constantly exemplified in the interior as well as on the exterior of our buildings.

A gratifying change is being made by our architects. Formerly, when the dwelling was constructed by the builders, they considered their work done, and their interest ceased upon its completion.

The coloring used in decorating a modern dwelling is always, consciously or unconsciously, controlled and dictated by the prevailing fashion. To gratify its whims, new shades and tints must constantly be created. These colors will appear in the latest textile fabric, and necessarily are introduced in the surroundings. The painter must become acquainted with these and introduce them in his scheme of coloring. In the selection and arrangement of his colors his degree of taste, refinement, and art will be seen. He may possess all necessary scientific and technical knowledge of his calling, his treatment with the brush be skilful, his judgment of design and proportion of same be perfect, but the entire effect may be destroyed, or at least marred, if the coloring does not receive the proper attention.

The successfully-decorated room receives its maximum amount of work, not in labor or material, but in thought and study. A certain shade in one place will appear entirely different when exposed and contrasted to different lights and surroundings. "Seeing is believing"; this trite saying aptly applies to a decorator studying a color effect.

The covering of walls with silk, tapestry and cretonne is on the increase for finer wall hangings. As a rule the effects are very beautiful, the good coloring and softer nature of the material easily according them with their surroundings; but its perishability, the ravages of moths and dust, the fading of the aniline dyes, will prevent the adoption of this material for permanent decoration.

Truly there is a soul in our art, or at least a finer feeling, not gifted to all, which must be disciplined and cultivated, for to be able to discern those subtler tones, to appreciate those minute differences in tints and shades, to feel the effect of warm and cool, or to distinguish between chaste and vulgar colors, there is something more than the technique of a craft required to be thus affected.

The more we are surrounded by beautiful and harmonious forms the more exacting becomes our natures, the greater our requirements, the higher our ideal. It is our education, our intelligence, our culture, that creates this natural demand for a higher art. We know there is no finality in art, but we must endeavour, on all occasions, in return for our labors, to attain the greatest amount of permanent beauty, and to strive, constantly strive, to reach the highest excellence, the position occupied by our old masters of the Fifteenth and Sixteenth Centuries.

The use of copper in decorative metal work is largely on the increase, by reason of the ease with which it can be used in various electroplating processes. The electrotyping of metal has been carried so far that entire shop fronts are constructed by this process. One of the ceilings of the Equitable building is made of electroplated copper on wood, which exhibits the capabilites of this beautiful method of interior decoration.

A good frieze for the wall was produced recently by a firm of decorators in the following way: A frieze was marked out on the wall by bands of narrow moulding two-and-a-half feet apart, thus preserving the depth of frieze. The paper of the frieze was the same as the paper on the rest of the wall, and along this frieze were arranged, at distances of one-and-a-half yards apart, and located at points about three inches below the top moulding of the frieze, small brass lions' heads, and from these heads was draped a chintz festooning all round the room.

The Ontario Department of Public Works has removed to the new Legislative buildings in Queen's Park, Toronto.

To measure plumber's work, says Lockwood's "Builders' Price Book," take the lead as cut and laid, by the superficial foot; the quantity of feet multiplied by the weight of the lead per foot, and divided by 112, will give the required weight.

In the case of a mortgagor who moved a house from the mortgaged premises to another piece of land owned by him but not covered by a morgage, the Supreme Court of N. Carolina held that the mortgagee's lien on building was not affected, and decreed a sale of the house on its new *situs* with leave of the purchaser to remove the building, there being no question as to the ownership apart from the claim of the mortgagor.

The famous "Leaning Tower" of Pisa, Italy, so celebrated in the annals of the world as one of the greatest of its many wonders, was begun in the year 1152, but was not finished until after two centuries had come and gone. It was erected as a sort of triumphal tower to celebrate the victory of the Pisans and the Normans over the Saracens, the two former having allied to drive the latter out of Italy. The fact that this old relic is now in the market and offered for sale to the highest bidder makes this item timely and appropriate. The old tower is circular in shape, 100 feet in diameter, 179 feet high, and is of pure white marble. It is divided into eight stories and has galleries at each story which extend entirely around it. As above mentioned, the entire structure is of massive marble slabs, the weight of which gives it a decided over-toppling look, the top hanging out, as it does, sixteen feet over the foundation.

SANITARY AND HEATING

HOUSE DRAINS.

We can remember, says the *Contract Journal*, when it was customary for architects to specify nothing less than 9 in. for the internal diameter of the main drain to an ordinary house, and sometimes a 12 in. pipe was thought necessary for a large mansion or warehouse. We are glad to think that smaller pipes are more generally adopted now. Yet we occasionally meet with architects who still cling to the prejudice in favor of large pipes, and some two years ago we knew a vestry surveyor who insisted upon a 9 in. main drain being laid to a common lodging-house containing some half-a-dozen water-closets, all discharging into a single 6 in. trough. To those who reflect upon the rapidity with which water finds its level, the danger of deposits being left in a 9 in. pipe is obvious. A 9 in. circular pipe, half filled with water, holds one gallon in every 4 in. of length, so that the orthodox two gallon flush from a single closet soon distributes itself in such a shallow stream as is totally insufficient to carry away the soil. A 6 in. pipe, half full, carries a gallon of water in 1 ft. 8 in. of length and a 3 in. pipe, half full, carries the same quantity in 3ft. 4 in. Of course it is advantageous for the soil to flow in narrow, deep channel. This is a reason in favor of pipes of an egg-shaped section, though the care required in setting the axis of the oval section vertical increases the cost of laying the pipes. The danger of small pipes becoming choked through an excessive flow of soil has been exaggerated. Prof. Corfield has found that even in large country mansions, with large areas and outbuildings, no main soil drain need ever be more than 6 in in diameter; and in Gwilt's "Encyclopæa of Architecture." (1888) there is instanced the case of a 10-roomed villa where a 3 in. main drain was used without inconvenience for many years.

The choking of a drain is caused not so much by an excessive flow of soil through the pipe, as by an insufficient or badly regulated flow, which causes deposits to accumulate. It has been observed that when a water-closet is situated low down, near the head of the drain, the latter is liable to become choked. This occurs through the gradual accumulation of solid matter. It certainly is preferable when the water-closet is situated at some height above the head of the drain. The advantage of this consists less in the velocity acquired by the soil in travelling down the soil-pipe, than in the breaking of the soil matter into small fragments, which are held suspended in the water. The velocity is useful to carry the soil through the trap, and after that a slight fall suffices to ensure a sufficiently rapid flow.

An insufficient fall to a drain allows time for solid matter to settle, because the water does not flow rapidly enough. On the other hand, it has been found that if the fall is too great the water runs away, leaving deposits of soil. According to Hurst, a velocity of 2ft. per second is the smallest that will keep a drain clear, but 3 ft. per second is required for a house drain. It has been calculated that this velocity can be obtained in a 4 in. pipe half full, with a fall of 1 in 100; in a 6 in. pipe, with a fall of 1 in 150; and in a 9 in. pipe, with a fall of 1 in 225. But there is great divergence of practice in arranging the falls of drains. Some architects favor falls of 1 in 60, some 1 in 40, and others 1 in 30. The regulations made by vestries exhibit differences of opinion on this subject. One London vestry states the minimum fall for drains at 1 in 60, another at 1 in 48, and a third at 1 in 40. We rarely find measures taken to guard against an excessive fall. We know one London vestry that requires the fall to be not less than 1 in 40, and provides that the whole of the available fall is to be made use of. The maximum fall may, therefore, be anything, and it may easily be such as to allow the water to flow away, leaving deposits of solid matter in the sides of the pipes. A plentiful flow of water is far more effective in cleansing a drain than a rapid fall, and the two-gallon flush, to which we are limited by law for each water-closet, ought to be supplemented by a further supply. A rain-water drain may advantageously be turned to account in flushing soil drain, especially if connected near the head of the latter.

A report obtained currency two or three weeks since that an association of manufacturers of plumbing supplies was to be formed to restrict credit, and in other ways to place the trade on a more satisfactory basis. Enquiries of leading manufacturers elicited the reply that they know nothing about such a movement.

MANUFACTURES AND MATERIALS

EFFECT OF TIME ON STRENGTH OF CEMENTS.

Baron de Roehmont, engineer of the Port of Havre, gives figures to show that the strongest briquettes, at two days, having a breaking strain of 147 pounds to the square inch, had a breaking strain of 318 pounds per square inch, after a period of 30 days. Other cements which had breaking strains of 157 pounds at two days increase to 661 pounds in thirty days. The weight or tensil strength of cements diminish when they have been kept in stock for some time. In the case of 15 cargoes of cement which came under his notice the weights, on delivery, were between 111 and 121 pounds per bushel, and the breaking strains were from 75 to 160 pounds per square inch in two days, 160 to 289 pounds in five days, and 339 to 460 pounds in thirty days. After being six months in store their weights were from 101 to 108 pounds, and their breaking strains from 38 to 114 pounds in two days, 112 to 195 pounds in five days, and 234 to 340 pounds in thirty days. The fall in weight and strength when the cement has been kept in store for a year is still greater. One cargo weighed on delivery 111 pounds per bushel, and its breaking strains at two, five and thirty days were 96, 230 and 271 pounds respectively. After the cement had been in store six months its weight was 106 pounds per bushel, and the briquettes made from it had breaking strains at two, five and thirty days of 109, 178 and 332 pounds respectively. After being in store a year the cement weighed 106 pounds per bushel, and the briquettes made from it had breaking strains at five and thirty days of 73 and 250 pounds respectively.

NOTE ON THE COMPRESSIVE RESISTANCE OF BRICK.

The writer has previously called attention to the fact that the flatness of the pressed surfaces greatly affect the crushing strength of cubes of brick or stone. The present note is written to present the results of some experiments made to determine the effects of different methods of preparing the pressed surfaces to the test specimens.

In testing some paving brick, the writer made some preliminary experiments by preparing the surfaces in five ways, viz.: 1, grinding as nearly flat as possible upon the convex side of an emery stone, and crushing between self adjusting, parallel, cast iron plates; , removing the irregularities of the surface, and crushing between blotting paper; 3, removing the irregularities of the surface, and crushing between straw boards; 4, removing the irregularities of the surface, coating with plaster-of-paris and placing under slight pressure until set (12 to 24 hours), and then crushing; 5, coating with plaster-of-paris which was afterwards ground down on a sand-paper disk, to the surface of the brick, so as to leave a minimum thickness with a perfectly flat surface, and then crushing.

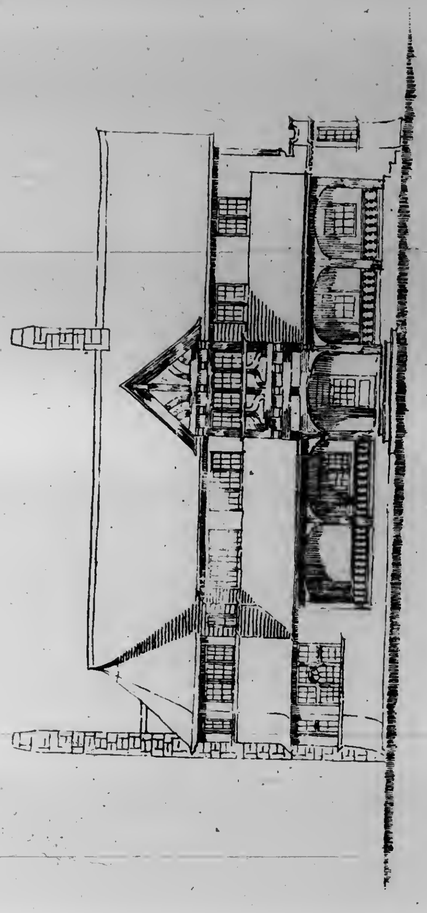
After a considerable number of experiments, it was decided that there was no great difference between the first three methods, while the difficulties in applying the last two were so great as to render them worthless. With a grade of brick which was quite uniform in quality, the first three methods gave 7,000 to 9,000 pounds per square inch as the crushing strength of cubes. The fairly close agreement of the results was considered satisfactory evidence that the method employed secured the full strength of the brick. Subsequently the writer decided to determine the strength of cubes when pressed surfaces were prepared with the greatest care. The samples were prepared on a rubbing bed at a marble dressing establishment, by the ordinary workmen, with instructions to secure perfectly flat surfaces. The brick were of the same grade as those referred to above, and many of the samples were the second halves of the brick used in the first experiments. The strength of the carefully prepared cubes ranged from 16,000 to 21,000 pounds per square inch, and averaged a trifle over 18,000.

The conclusion derived from the two series of experiments is that an almost imperceptible difference in the flatness of the test specimens makes a very great difference in the strength. Obviously this difference is greater the harder and more brittle the brick or stone. It is perhaps well to repeat that tests of compressive resistance of blocks of stone or brick are useful only in comparing different samples, and gives no idea of the strength of masonry constructed of these materials.

It is interesting to note that Rankine and Trautwine, standard British and American authorities, in editions of their engineers' manual published a few years ago, give the crushing strength of the best brick at 1,100 and 4,000 pounds per square inch respectively, while there has recently been tested in the university testing laboratory three lots of brick which averaged from 15,000 to 18,500 per square inch. The difference is probably due mainly to improvements in the manufacture of brick. The crushing strength of granite, when tested under similar conditions, is from 12,000 to 20,000.—IRA O. BAKER, Professor of Civil Engineering, University of Illinois, in the *Technography*.

The Central Bridge Works, of Peterborough, has been succeeded by the Central Bridge and Engineering Co., incorporated, with a capital stock of $200,000. The company will manufacture steel and iron bridges and structural iron and steel for all purposes.

Messrs. Merchant & Co. are calling the attention of their customers to the fact that they have ceased to handle "Gilbertson's old method" brand of roofing plates, the quality of which, in the opinion of many of their customers, has deteriorated of late. They are now offering a heavier and better plate manufactured in their own works in Philadelphia.



FRONT ELEVATION

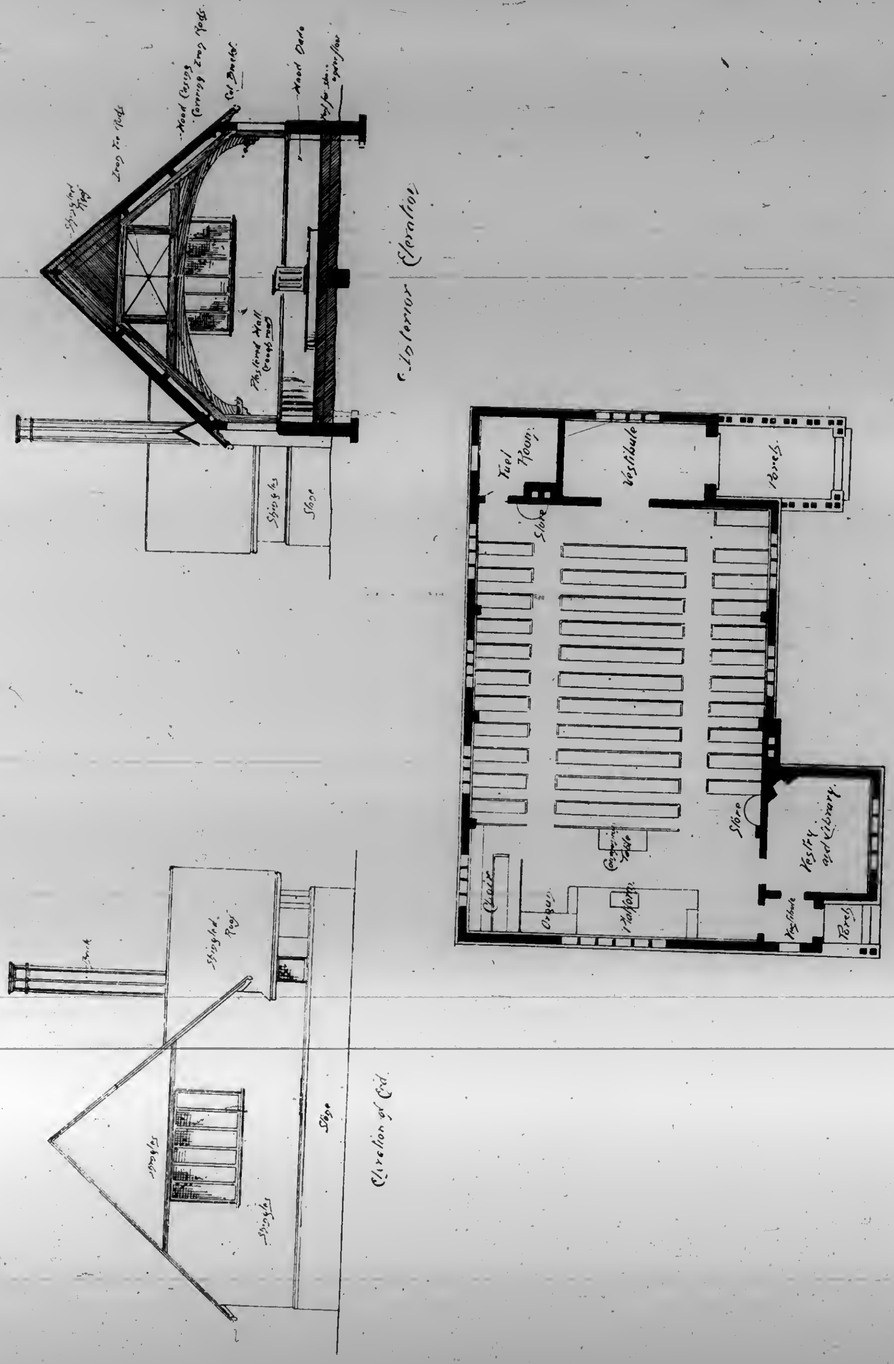
GROUND FLOOR



Presbyterian Church Competition.

Design Submitted by "John Knox." (Arthur E. Wells) Toronto.

CANADIAN ARCHITECT AND BUILDER.

VOL. V.—NO. IX TORONTO AND MONTREAL, CANADA, SEPTEMBER, 1892. PRICE 20 CENTS $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),
PUBLISHED ON THE THIRD SATURDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,
14 King Street West, - TORONTO, CANADA.
64 TEMPLE BUILDING, MONTREAL.

SUBSCRIPTIONS.
The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.
Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.
Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1892.

PRESIDENT	S. G. CURRY, Toronto.
1ST VICE-PRESIDENT	KING ARNOLDI, Ottawa.
2ND VICE-PRESIDENT	F. J. RASTRICK, Hamilton
TREASURER	D. B. DICK, Toronto.

COUNCIL:

WM. G. STORM	Toronto.
DAVID EWART	Ottawa.
S. H. TOWNSEND	Toronto.
JOHN E. BELCHER	Peterborough.
EDMUND BURKE	Toronto.

REGISTRAR AND LIBRARIAN:
W. A. LANGTON - Merchants' Bank Building, Toronto.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1892.

PRESIDENT	F. X. BERLINQUET, Quebec.
1ST VICE-PRESIDENT	VICTOR ROY, Montreal.
2ND VICE-PRESIDENT	J. NELSON, A.R.C.A.
SECRETARY	C. CLIFT, Montreal.
TREASURER	W. E. DORAN, Montreal.

COUNCIL:

A. T. TAYLOR, F.R.I.B.A., R.C.A.	Montreal.
A. C. HUTCHISON, R.C.A.	Montreal.
M. PERRAULT	Montreal.
A. F. DUNLOP, R.C.A.	Montreal.
ALPH. RAZA	Montreal.
J. F. PEACHY	Quebec.

TORONTO BUILDERS' EXCHANGE.

BOARD OF DIRECTORS:

WM. J. HILL, President.	JOHN ALDRIDGE.
GEO. MOIR, 1st Vice-President.	BENJAMIN BRICK.
GEO. OAKLEY, 2nd Vice-President.	WM. PARK.
JOHN L. PHILLIPS, Secretary.	JAS. CRANG.
DAVID WILLIAMS, Treasurer.	M. MURPHY.
	J. LISTER NICHOLS.
	WM. PEARS.

THE introduction of iron and steel skeletons for the support of large buildings is said to have lessened to a very large extent the demand for brick.

REFERRING to the illustration of the proposed new union station at Toronto, published in this journal, the *Architectural Era* says: "We had the pleasure of seeing the original drawing in Toronto recently, and it seemed to us to be one of the most pleasing compositions yet produced in the Province."

A New Hampshire granite manufacturer states that it will take ten years for the industry to regain the position which it occupied prior to the recent strike of granite cutters. It would be interesting to know what advantage the strikers expect to derive as the result of the injury which they have been the means of inflicting upon this important industry.

THE next number of the ARCHITECT AND BUILDER will be issued from new publication offices, Rooms 106, 107 and 108 Confederation Life Association Building, Richmond and Yonge streets. We shall there enjoy better facilities for the carrying on of our work, and shall be pleased to see as many of our friends as can make it convenient to visit us.

The opinion of the citizens of St. John's, Nfld., was that the cathedral destroyed in the recent conflagration, was fire proof. Consequently when the fire broke out, the building was made the storehouse for furniture and other combustible materials. A burning ember blown through the open door set fire to these materials, and belief in the ability of the structure to withstand fire was quickly dissipated.

SEVERAL accidents, some of a fatal character have lately resulted from the breaking down of derricks while under strain. There appears to be need for more careful examination of such apparatus, to give every possible assurance that it possesses the requisite strength. Equal care is required on the part of those who may be entrusted with its operation, in order that the lives of workmen may not be carelessly sacrificed.

The time has almost arrived when the Toronto Architectural Sketch Club should resume its regular meetings. It is to be regretted that owing to the prevailing dullness in building operations and other causes, several of the leading spirits of the organization have recently removed from the city. While the loss of these members will be severely felt, others should be found ready to take their places, and display like activity on behalf of the progress of the Club.

WHILE congratulating Messrs. Strickland & Symons upon having received the commission to prepare the plans and superintend the erection of the new union railway depot at Toronto, and the railway companies and the city upon the fact that the work has been entrusted to such capable hands, we may nevertheless point out that an opportunity existed for a most interesting competition. The subject is one which might well have engaged the thought of all the leading architects of the country. The palace hotel which it is said to be the intention of the C. P. R. to erect opposite to the new depot, might also form the subject of such a competition

A DECIDED impetus has been given to the movement for the reduction of the hours of labor, by the signing by the President of the United States of an act recently passed by the Senate enacting that eight hours shall constitute a day's work on all public works, except in cases of extraordinary emergency. Any government agent or contractor who shall violate this law, will be liable to a fine not exceeding $1,000, or to a fine and imprisonment, at the discretion of the court.

The Toronto Builders' Exchange, a list of whose officers may be found in this and future numbers of the ARCHITECT AND BUILDER, is still adding to its membersship and in other respects proving a success. The exchange has delayed taking possession of its new and handsome suite of rooms, pending the paving of the southern portion of Victoria Street. This part of the street having now been asphalted, no time will be lost in making the change of premises, and in a short time the members of the Exchange and their friends will be asked to take part in a formal celebration of the event.

LERNARD HEUKLE, a resident of Rochester, gravely announces his purpose to erect "the largest building on earth," in the shape of a power house at Niagara Falls. The building, which is to cost about $35,000,000 is expected to pay six per cent. on an investment of $256,000,000. It is a fortunate thing for the management of the World's Fair that several years will be required for carrying out Mr. Heukle's plans. Otherwise visitors might be expected to give the Fair the go-by in favor of the greater exhibition at the Falls. The architectural world will anxiously wait for the publication of the plans of this structure which is to dwarf the pyramids.

YOUNG architects who have not been practicing long and whose clientele is not large, often find it profitable in more than one sense to do some work outside of architecture, for instance, designing of various kinds. Wall papers, bindings for books, title pages, photo engraving and even furniture, all offer a field for a clever designer in which to add to his income while it does not detract in the least from a proper professional dignity. Young architects whose means are small too frequently "go in" for the publication of works cootaining "designs for the million" to the great disadvantage of themselves and of their profession. By inquiry they might find many fields more profitable and less *infra dig.*

It would, no doubt, lead to the avoiding of defective construction, such as that referred to in our last issue, if there was an enactmeot in force in Ontario, similar to that which exists in Great Britain and the Province of Quebec. In Quebec, the law holds the architect and the contractor jointly responsible for the safe construction of buildings, for a period of ten years after their completion. An instance has come to our notice wherein a Montreal architect was compelled to pay between three and four thousand dollars, in consequence of the collapse of a building erected under his supervision some five years ago. Unfortunately for the architect in this case, the contractor had placed all his property in the name of his wife, and it was not possible to compel him to contribute his share of the amount.

IN another column will be found an article descriptive of experiments in the use of electricity for heating purposes, which have recently been in progress at Ottawa, Ont., together with illustrations of the devices employed. So successful have these experiments been, that the new method of heating is soon to be put to a practical test on an extensive scale. The result will be watched with much interest, more especially in view of the advancing price of coal. A vast waste of money and labor is involved in our present methods of heating. It may be regarded as certain that there will be substituted for them in the near future a method not less efficient and more cleanly and economical. It is by no means unlikely that electricity will be the chief agent in the reform.

A CANADIAN gentleman who lately inspected the buildings in course of construction for the Columbian Exposition, became firmly impressed with the idea that there was great danger of their being destroyed by fire during the progress of the Fair. To the frame-work of the buildings is nailed diagonally rough boards, which in turn are covered with a material called "staff." Our informant states that should a spark find its way inside this hollow wall of highly inflammable material, it would be almost impossible to check its progress. The vast extent of the buildings, besides increasing the probability of fire, would greatly add to the difficulty of subduing it. The extensive precautions being taken against the possibility of fire, serve to indicate that the management are not unaware of the dangerous conditions above referred to.

A CONTRIBUTOR to an English professional journal recommended the use of a solution of common salt to prevent the accumulation of the unsightly efflorescence that so frequently appears on the surface of brickwork. The usual remedy, if such it can be called, is to apply a solution of muriatic acid, but it is by no means absolutely effective. This trouble has bothered architects and builders for years, and so far no remedy has been found. An explanation of the efflorescence is simple enough. When a clay from which a brick is made contains magnesian lime, the trouble will occur. A brick being absorbent, the water soaks in, and dissolving the magnesia, effloresces on the surface of the brick. Why should not architects specify that no brick is to be used that will effloresce. The result would simply be that brickmakers would cease to use clay that contained magnesian limestone.

ARRANGEMENTS are being made for the annual meeting of the Province of Quebec Association of Architects, which will take place in Montreal on the 29th inst. We hope that every effort will be made to ensure the success of this meeting. A feature which has been absent from former meetings, has been the reading of papers on architectural subjects; such papers, when read at the meetings of the Ontario Association, have awakened profitable discussion, and have been of lasting benefit to the members. We have no doubt that similar results would follow the reading of papers at the meetings of the sister Association of Quebec, and we are pleased to see that a departure is to be made in this direction at the approaching meeting. It will be remembered that the Ontario Association, at its last convention, had the pleasure of a visit from Messrs. Hutchison and Clift of Montreal, representing the Quebec Association, and it is to be hoped that the desire for a better acquaintance thus manifested by the Quebec Association will be reciprocated by the architects of Ontario. The Ontario Association should appoint some of its members a delegation to Montreal on the 29th inst., and these delegates should go prepared to offer such advice and encouragement to the younger Association as will tend to awaken the enthusiasm of the members for the carrying out of the objects which the Association was formed to accomplish.

IT is surprising that concrete is not used to a greater extent than it is. There is so much material, such as slag from the iron works, available for the purpose that the cost of concrete should be quite low. Although pebbles are employed for ballast in making concrete, with the addition of sand and cement or lime, any hard material answers equally as well; in fact concrete gives ample opportunity for the utilization of the waste products of many industries. Of course a hydraulic cement such as Portland is the proper thing to use in making concrete. It not infrequently happens, however, that the expense is too great, and lime is used instead. It is of great importance to remember that pure lime —that is one that will not set in the presence of water— is practically useless for this purpose. Pure lime, called also rich lime because of its rich or fatty appearance when slaked and mixed, is only suitable for interior work such as plastering. The proper limes to use for concrete and mortar are those of the hydraulic class, called also "poor" limes. These have proportions of material other than lime in their composition, such as iron, silica, etc., which gives them the property of setting under water. A "pure" lime can readily be distinguished from a "poor" lime by the fact, that while the former gives out a good deal of heat and steam in slacking, the latter does not. Limes used for building purposes too frequently lack the hydraulic qualities.

THE new building ordinance which has recently gone into operation in Boston, and which is regarded as a model of its class, provides that no buildings, excepting wharf sheds and grain elevators, shall hereafter be put up a height of more than 70 feet or an area greater than 10,000 square feet, unless strictly of incombustible materials; that no building, to be used above the first floor for mercantile, manufacturing or storage purposes, can be put up having a height of more than 45 feet unless constructed wholly of incombustible material or with floors of grooved planks at least two inches thick; that no building of any kind or material will hereafter be allowed exceeding a height of 125 feet, and brick, stone, or iron buildings must have party or bearing walls of brick carried at least one foot above the roof. These must be plastered directly upon either solid masonry or metal lathing. All columns or beams bearing weight must be protected by brick, terra cotta or other incombustible material. Doorways in partition walls cannot exceed two upon each floor, and these must be protected by double, tin-covered doors hung to iron frames. Buildings, except offices and dwellings within 30 feet of an exposed opening, must have fire-proof shutters, and all elevators must be of solid brick, or other incombustible material, and the openings furnished with metal-covered doors.

Now that the agreement between the city of Toronto and the Railway Companies has been signed and the works put in hand it is time to consider what may be done to improve the appearance of the water front. No one who has seen Toronto from the water, will say that there is not plenty of room for improvement, and we are inclined to think that it is not generally known as it might be that the proposed water front park is not part of the programme now. The new street which is to begin at the waterworks and run east along the whole front of the city, behind the wharfs and docks, at present promises no better an appearance than exists with the esplanade. After a few years, probably, warhousces and such buildings will be erected upon it, and these, though no doubt very necessary, are not likely to be noted for architectural beauty. We can see no very great reason why that large area, which was to have been the site of a C. P. R. station—south of the tracks and west of the present steamer landings and sheds—should not be made into a public garden or park, with an "embankment," on the principal of the Thames embankment, London, with a handsome water wall. This park would be reached by York street and the bridge which is to be constructed to give access to the water over the tracks, so that there would be no risk to the public in having to get to the south side of the tracks. It is all very well to urge that the Island Park is being made into a resort which gives great delight and immense advantages to the citizens, but it costs ten cents to get there and back every time, while here is a fine space, which, if made into a park would be a boon to a great many and would be a decided improvement to the appearance of the city We may mention in passing, that it is a pity some rather less commonplace name could not have been found for the new street; "Lake Street" is not only commonplace but senseless, as it has nothing whatever to do with the lake. "Bay Street' would have been more *appropriate* perhaps, but there is already a street of that name, and perhaps such a name would have been equally poor. We leave it to others to choose a name, but register our objections to "Lake Street." A park here would be a great advantage to travellers, who while waiting for trains could rest in the gardens in preference to the waiting-rooms of the station. Toronto water-front needs some redeeming feature; it can never be like Montreal's quay or even that at Kingston, and at present it is only one degree better than Hamilton. Toronto is an entirely different class of city to Montreal, and a garden front at the point where all incomers arrive, whether by boat or train, would be decidedly in keeping with the character of the city.

CLUB HOUSE FOR THE TORONTO ATHLETIC CLUB.—E. J. LENNOX, ARCHITECT, TORONTO.

CHURCH OF ST. JOSEPH, ST. MARYS, ONT. POST & HOLMES, ARCHITECTS, TORONTO.

MANTEL IN PROVOSTS ROOM, GLASGOW MUNICIPAL BUILDINGS.

COTTAGE AT SCARBORO', ONT.—E. B. JARVIS, ARCHITECT.

The whole of the exterior is shingled from roof to the ground. The shingles are stained as follows: roof, red.; gables, raw sienna; and ground floor a grey tint. The wall and ceilings inside are stucco finish, tinted. The hall is sheeted up to the frieze, then stucco frieze and ceiling.

THE TORONTO COURT HOUSE DIFFICULTY.

THE Toronto Court House has been at home of almost unceasing interest from one cause or another ever since its inception. In the face of the many stories in circulation, and the difficulty of getting at the actual facts, we have up to the present refrained from commenting upon the case. The crisis having at last been reached by the entry by force of the architect upon the premises and the exclusion of the contractor, we need hesitate no longer. What the result of the trial of the case which is to take place on the 26th inst., may be, we of course cannot foretell, but it is certainly time that such a grave scandal as the matter had become should be ended. There is more than one question at issue. The works are two years behind time, and the contractor, whether rightly or wrongly we cannot pretend to say, has refused to remove certain stones, built into the wall, which the architect has condemned, giving as his reason that they were passed by the architect as sound before being placed in position. We regret the stand made by some of the aldermen, who cannot from the nature of their calling be expected to be versed in such matters, but who would nevertheless try to settle the difficulty by ways totally unsuitable and contrary to the strictly business principle that should and must be adhered to. Contracts exist between the city and architect, and between the city and the contractor, and the terms of these documents, ought to be sufficient to meet the difficulties which have arisen, and no doubt they are. Advice has been obtained by the city and also by the architect, as to the legality of the proceedings they contemplated taking. Little can be said pending the trial of the suit brought by the contractor, but for the honor of all parties concerned, it is to be hoped that the matter may speedily be settled, and the work proceeded with, as thus far the court house has been fruitful of little else than trouble. One thing is certain, viz., that the stone is unfit for the position in which it has been placed. One of the questions which the courts will be called upon to decide, will be, who is to blame for the stone being built into the wall and left there for several months, and then found to be in a state of decay. Stone that will decay in so short a period could never, we should suppose, have been passed by an intelligent architect or clerk of works, or be used for face work by a competent builder. The matter may hinge upon the quality of the stone selected. It is understood that samples of stone were submitted by all the contractors who tendered for the work; it becomes a question whether or not a sufficient quantity of the stone chosen, of a quality similar to the sample, can be procured. This important information should certainly have been obtained before the contract was let. We understand that it is the contention of the architect, that there is sufficient stone of good quality to be had from the quarry from which the condemned stone was taken. The evidence on both sides of the dispute, will be looked for with much interest, and it is much to be desired that a final and satisfactory settlement of the difficulty will be the outcome.

The well-known architectural firm of Langley & Burke, Toronto, has been dissolved. Mr. Langley will continue the business of the firm, while Mr. Burke has assumed the business of the late W. G. Storm.

The Superintendent of Water Works, Toronto, recommends that in the future water be supplied free to builders. It having been found impossible to collect more than about fifty per cent. of the water rates charged against builders, it is deemed unfair to honest builders to continue the system.

In our August number was published the results of recent examinations of the Province of Quebec Association of Architects, together with copies of the examination papers. In this connection the fact should have been explained that these examinations were not to qualify persons for registration but simply to admit students to study. There were no candidates for registration.

It is in the perfection of the details of sanitary work, in the careful observance of every essential requisite that will promote cleanliness and exclude all health destroying elements, that the competent master plumber reveals his skill, and it is just in these very points that we look for the difference between good and bad plumbing.

ODDS AND ENDS.

IN building brick houses in positions where they are not protected by surrounding property do not forget that hollow walls will add greatly to the convenience of the occupiers. They will render the house cooler in summer and warmer in the winter, and will assist in materially in keeping the house dry. The cost of hollow walls is only very little higher than that of walls built solid.

* * *

During the hot weather that has prevailed of late it is of great importance in erecting buildings in stone or brick to thoroughly wet every stone or brick before it is laid. The water not only removes any dust that may have accumulated and would prevent the mortar adhering, but it causes a much better adherence between the bricks or stones and the mortar than would otherwise be the case, because of the tendency to suck up moisure in dry and hot weather. This may seem at first sight an item of little importance, but there is more in it than may appear.

* * *

What is the best paint for general iron work used in the construction of a building? Many prefer metallic paint, but experience has shown that for practical purposes nothing is better than red lead. The first cost is somewhat greater, but the increased durability renders it cheaper in the end. It should be added that the red lead should be applied directly to surface of the clean iron, not on top of a coat of oil or of metallic paint as is sometimes done.

* * *

A method of finishing doors and other woodwork that appears to be coming into favor is the following: The doors are of hardwood and are filled with a very dark filler; they are then polished in wax, when they present a semi-dull appearance that is somewhat pleasing. Ornamental headed nails made of white metal are then driven in the doors at regular intervals but in a way to form a somewhat elaborate design of scrolls. Each of the doors leading into the same hall are finished in different designs as far as the nails are concerned, but the prevailing color is the same throughout. The effect is very good.

* * *

A paragraph that went the rounds of the architectual press about a year or so ago was to the effect that in Norway the custom is, in building in winter, to use mortar while it is hot, after slaking, with the object of preventing the mortar from freezing before it has time to set hard. The item is plausible enough, but the usefulness of the information is destroyed by the fact that lime that evolves much heat is entirely unsuitable for the use of making good mortar.

* * *

Painting is perhaps less understood by builders and architects than other branches of the building trade. For instance in finishing in the natural wood specifications frequently call for shellac and two coats of varnish in jobs where such a finish is not required. Shellac is probably the best first coat for hard pine that there is, but is not too expensive for ordinary work. "Liquid filler" or surfacer is largely used as a substitute in the United States and gives general satisfaction while saving at least one third of the cost, because the liquid filler is practically a varnish although it contains silex, starch or other substance that fills up the pores of the wood and stops suction. A little point that is not generally known even among amoong painters is this: To produce the best results use liquid filler for the first coat and add about one third of the filler to the second coat. A third coat of varnish just as it comes from the cans will make a very good job. The writer recently saw a church the walls and ceiling of which were finished in pine that had been treated in the way described with very satisfactory results.

FIRE ESCAPES FOR PUBLIC BUILDINGS.

QUEBEC, AUGUST 19th, 1892.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—New York's and more recently Boston's new building law, as noticed and commented on in late issues of the New York *Engineering Record*, contain many pertinent provisions as to the safety of buildings against accidents by fire, or due to faulty construction; but I have not yet seen anything in in them or in those of any other city, which thoroughly provides for escape in case of fire, from the upper tiers or galleries of theaters, assembly and lecture halls, academies of music and the like, or from the upper floors or stories of factories, colleges, convents, asylums, hotels and boarding or even tenanted houses, nor, in a word, from any building where there are large assemblages of human beings and especially when the old and infirm have to be dealt with, as well as the helpless infant.

Regarding such buildings, a provision of the "Boston Act" is that they shall have from each apartment (which, of course, also means from each floor or story) two independent ways of egress, one of which shall be enclosed in brick walls and shall have no interior openings other than the doors of the apartments from which it is an exit.

Now there is certainly no absolute safety in this proviso of doors opening from the inside into said stairway; for even though the enclosure be of brick and the stairs of iron, stone or other incombustible material, and that flames from below could therefore not run up through such a stairway and endanger the floors above, still the fact of any communication at all between the stairway and the inside of the building would allow all of the heated air and gases from the burning portions of the building to pass upward through such a well or shaft, and thus effectually cut off retreat in that direction.

On the contrary, any direct communication between the interior and the stair-case should be studiously avoided. The stairs should only be reached by passing out from the apartment on to an outer unenclosed landing, or open to the sky, and thence to the stairway; and as I proposed some years ago in a paper read before Section III of the Royal Society, I am still of the opinion and maintain that there is no other solution possible in the case of escape from a single or double series of rooms in a hotel or boarding school, etc., opening on a corridor with stairways at each end thereof, allowing the heated air and smoke from below to ascend and fill the passages, thus cutting off escape in the direction of their length, than by egress from each and every rear window of each and every floor above the first or ground floor, by stepping over the sill on to a continuous iron balcony (narrow and with lattice floor not to obstruct light to the window below) communicating with the stair-way—one or more according to the extent—the occupants of the front rooms having only to cross the corridor and escape through the window of the rear room opposite their own.

These stair-ways when in the rear and leading down to an interior court enclosed on all sides, should communicate with the open, the front of the building of street, by a fire-proof passage-way leading from rear to front, and as such passage-ways need not necessarily be more than of mezanine height, the exterior could be reached and the street level attained by a short flight of iron steps, without in any way cutting off communication between any of the ground floor rooms or corridors.

The only argument I have heard adduced against these continuous balconies all around the interior courts of a hotel, is on the score of want of privacy in case of a person from any one of the rooms prying into a neighboring apartment; but as there is not supposed to be any attraction towards the rear, the difficulty might easily be got over by posting in each room among other rules and regulations to be followed by the guests, "No access to rear galleries allowed except in case of fire" with the addition of curtains or frosting to the lower half of sash to render peeping in a profitless endeavour.

Where, as in a theater or concert hall, escape must be looked for in the opposite direction or towards the street or exterior, the same continuous balconies or verandahs can be made an ornamental feature of the several facades, or of one or more of them on the level of each and every tier of inside gallaries or boxes, as lately done (I do not say in obedience to my suggestion, though sometime after I made it public) in a theater at Antwerp in Flanders, where each of the five tiers of inner galleries communicates by some 25 doors or openings radiating from the auditorium with a corresponding series of outer balconies reaching first tier level by fixed iron stair-ways, and thence the street by folding stairs immediately detachable on the mere pressure of a foot spring, or where the first tier level may easily be jumped from without danger to life or limb; the non-existence of fixed stairs from street level being of course a preventive against access to the building excepting through the ingress door where tickets of admission are collected.

Such a system of fire escape galleries and stairs and passages I have combuted not in any case to necessarily exceed from 3 to 5 per cent. of the total cost of any building it might be applied to.

CHAS. BAILLAIRGE, Architect, etc.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER).

Following is the Program of the annual meeting of the Province of Quebec Association of Architects to be held on the 28th and 29th of Sept., in the rooms of the Association, 186 St. James St.:—

Thursday, 28th.—Forenoon—Annual meeting at 10.00 a.m.—reading minutes, report, &c.; President's address; election of officers; other business. Afternoon—2.30—Reading of papers by members. Evening 8.00—Annual dinner at the City Club, St. James Street.

Friday, 29th, 10.00 a.m.—Meet at rooms of the Association and drive to Victoria Hospital, new buildings of McGill College, and new High School. Afternoon—Visiting art collections, buildings, &c., at discretion of members.

THE VERANDAH IN AUSTRALIAN DOMESTIC ARCHITECTURE.*

WHAT feature has more importance and prominence in the designs of our houses, or is a more useful adjunct to the necessary living and sleeping-rooms of the plan than the varandah? Such has been the effect of its constant use on the public mind that no matter how good a design is or how masterly its details, if the verandah is omitted or even in an unconspicuous position, the public object and say, "What a bare-looking building!" or "It looks more like a State school than a house." In treating of the subject one naturally divides it into two parts—first, the practical uses and position of the verandah with reference to the plan; secondly, its treatment as an architectural feature.

The position of the verandah in respect to aspect is one of the chief points for consideration under the first head. The protection of the northern and western walls and windows from the hot summer sun usually decides its position, although for a summer evening lounge the western aspect is absolutely useless. In the cooler weather it might be so used, especially if the prospect is good, although the northern aspect will always be found more serviceable. Besides affording a protection to a building from the heat of the summer sun the verandah also serves to shield the walls from driving rain, such as we had experience of last July, which seems capable of penetrating almost any exposed wall of ordinary thickness. In the use of verandahs for winter exposures it must be always borne in mind that every room in the house should, where possible, receive the sun's direct rays into it during some period of the day, and that the more the southern and eastern walls of a house are exposed to the light of day the healthier will the house be. I think that even the rooms facing north and west should be designed so as not to be too closely sheltered from direct light, and that some means of introducing light above the level of the verandah roof or by glass skylights in the roof (opposite the windows of the rooms) ought to be made use of on the darker sides of the house if covered by verandah or balcony. By such means, and the use of movable blinds or shutters, the lighting and cheerfulness of a room could be completely under control, and many rooms cold and dark in winter brightened and made more habitable, whilst features might be made of the lighting in such a way as to improve the design. An illustration of a house was published some time ago in a professional journal in which this plan was adopted. So far, I have only been taking into consideration the lean-to shade so generally adopted here which does duty both for a protection to the house, an open-air living room, and as often as not simply a source of pride to its owner, especially, I am sorry to say, if showing a lavish display of cast-iron vegetation. It is to our American cousins that we are indebted for the most thoughtful arrangement of the verandah as regards both practical use and appearance. In many cases it can hardly be called a verandah; "piazza" is the name they give it, and it forms what really is an open-air living-room of rectangular plan and independent roof. It is open on three sides, but can easily be enclosed at pleasure by means of blinds or shades. It is usually on a secluded side of the house and facing the garden, approached from a side-door or garden entrance, and has the advantage over our usual narrow form of being wide enough to allow all to sit face to face. For the summer weather nothing seems more adapted to this climate, and yet it has come very little into use, people preferring the long narrow strip of floor to the roomier plan. As to the balcony, although most of the foregoing applies to both verandah and balcony, it is of course not so much used as an open-air resort, being on the bedroom floor and in a more private position. It therefore may be of smaller area and accessible both from rooms and from some public thoroughfare. Its prospect, of course, will influence its position, but the protection it affords will be its chief use.

Having thus far only dealt with the verandah as a convenience, I will next turn to its treatment as an architectural feature, but before doing so would like to draw your attention to its appearance and use in the styles which are the basis of the architecture of the present day. It is not necessary to go further back than the Greek temples, the colonnades of which are familiar to you as their chief embellishment, as well as being a convenient shelter from sun or shower. The same, of course, are found in the Roman examples, sometimes in the form of a portico, and sometimes in the complete peripteral arrangement. In the houses we find the prototype of the Gothic cloisters in the peristylum, a central open court with a fountain in the centre and a covered colonnade all round, where sun or shade might be enjoyed at pleasure. This feature became the cloisters of the Gothic, in which the ecclesiastics took their exercise, and on which the Gothic architect displayed his most elegant taste, if not his highest genius. These are found connected with nearly all religious establishments of the Middle Ages, surrounding as they did in old Roman houses a central square or garden. These cloisters, or rather the arcades dividing the cloisters from the open squares, exhibit some of the finest examples of Romanesque, with their richly carved shafts and arches. The Moors, too, loaded this feature with a lavishness of ornament, brilliance of color and gracefulness of form that have been the admiration of us ever since. The private courtyard, with its surrounding cloister or arcades, remained in extensive use in Italy and Spain right throughout the Renaissance, as many of the palaces testify, whilst the external colonnade is also to be found, as for example in the Gothic palace of the Doges at Venice, and the later Renaissance of the library in the same square. Beyond its introduction in the porticoes of the Renaissance, the external use of this feature did not find much favor in England. Sunlight was too highly valued, and obstructions to it were avoided. There is, however, one very curious instance of its use to be found in Chester, where the first floor walls right along the streets are recessed some 8 or 9 feet back, making a covered walk which is continuous along the top of the ground-floor shops. The storeys above, which are supported on heavy wooden posts, keep the line of the ground floor and form a roof over the first floor balcony. This peculiar feature of Chester struck me as very curious when I first saw it, and as far as I know it is unique. It would be interesting to hear what was its origin if any present can explain it. It is in the East, in India, China, and Japan, however, that we have the most extensive use of the outside verandah. There its necessary application to the smaller buildings and houses brought it into use in simpler and lighter forms than we find in Europe. The materials, too, being less massive, tended to alter its appearance to a less imposing structure, and although the large temples and palaces were surrounded by ponderous pillars and elaborately-covered approaches the houses, especially in Japan and China, were of very light construction, little more than open-air verandahs or living-rooms separated and enclosed by screens and mats. From the architecture of these nations a good deal could be learnt as regards the design of picturesque and effective verandahs, which in their hands are always artistic and usefully simple.

As external features the verandah and balcony have great importance, many domestic buildings here carrying all their architecture on their verandahs, while their prominence and the strong effects of light and shade which they afford often make them the governing features of the design. In many of our larger mansions they form arcades or colonnades surrounding the building, with columns and orders of the same material as the main block and after the manner of the Italian Renaissance, and if of good design give an imposing and substantial appearance. They are seldom, however, treated with much picturesqueness in this style, and so have a formal and somewhat depressing effect (especially if carried out in stucco), which suggests a similarly formal interior. The less stiff intermixture of Classic detail and Gothic grouping which we find so picturesquely blended in the later Elizabethan architecture of such buildings as Holland House,

* From a paper by Mr. W. M. Campbell, read at a meeting of the Victorian Institute of Architects, and published in the *Australasian Builder*.

where the arcaded verandah is extensively used, should afford some useful hints as to how to treat our large houses with piquancy as well as dignity. The most objectionable form that this most useful adjunct to a house has taken, and one peculiarly Australian, is that in which ornamental cast-iron is such an important factor. Every portion of these erections is as a rule a jar of the artistic nerve. When one comes across such examples as I have sometimes had the fortune to meet with in my walks, as, for instance, brackets composed of a few ragged cast-iron leaves, painted a brilliant green and forming a perch for a cast-iron cockatoo in natural colors; or, what is more common still, a verandah front representing a sort of nightmare of Ferntree Gully, one begins to look apprehensively at the gardens in fear of alighting on a crop of cast-iron shrubs. I do not wish you to understand that I think that cast-iron is a material which cannot be treated artistically, though as a matter of fact it very seldom is, and never when any attempt is made to copy the delicate and flexible forms of nature. The necessary slenderness of the supports, and the wide spacing of the posts, make a design in this material structurally unpleasant to the trained eye. From the consideration of this class of design, which will doubtless hold its own in this city for a long time to come, one can turn with relief to the simpler and less pretentious forms which are now beginning to show themselves in our suburbs. Of these developments one of the principal is that of the bungalow form, in which the sloping roof of the house is continued to cover the verandah also. With these designs the posts require to be simpler and heavy with simple cut brackets in keeping with the style. In this style, too, I should prefer to see a change in slope of the roof at the junction of the verandah and house roofs, to accentuate the position of the house walls and to take the apparent weight of the roof off the verandah posts. Glancing at some of the designs published in the American journals we find great variety of treatment, from the heavy roof supported on rough stone piers to the elegant Classic wooden columns and orders developed from the early colonial architecture of the country, and all having a substantial and well-designed appearance, so often wanting in the work here. In some cases the treatment of the verandah seems too fussy and the striving after the picturesque too obvious to be altogether pleasing, but there is great originality and careful thought shown in a great number of designs. It is noticeable that the continuous balcony is not a common feature, with the result that the main building stands up boldly, and is an object for architectural treatment of the boldest kind, whilst the verandah roofs coming lower down give greater protection and allow of better proportions than when the balcony is introduced. In the American work there is much more unity in design between house and verandah than is usually to be found in the work, resulting to a great extent from the substantial manner in which the former is carried out.

INCANDESCENT WIRING.

By C. W. Swoope.

THE proper installation of wires for carrying electric currents is a subject which has engaged considerable attention ever since electric lighting first became practical. Since this time it is of course natural that there have been progression and improvements in the methods of electrical distribution, as well as the manner of insulating the conductors. Insulation is the vital principle of the subject, and all efforts, which indeed have been many, interesting, and expensive, have been tending towards a perfect bridling of the "subtle fluid." For ordinary currents and voltages the present methods come very close to the object, but the subject is still fresh and unsolved in the minds of those experimenting with alternating currents of high potentials. The question is still asked by property owners, architects and builders, "Can electric lights be satisfactorily installed with safety from fire," and the answer comes without hesitation, "yes, if the underwriters, requirements are strictly fulfilled and the installation is put in by competent parties using the most modern appliances and material." Verily "competition has been the life of the electrical trade" in its true branches, especially in the manufacture of appliances and construction work, the former producing many forms and grades of apparatus to answer a single purpose, and the latter various modes of installation. Nearly all the difficulties and troubles in electric lighting stations or consumers' houses have been caused by defective wiring, and upon this part of the system more than upon any other depends the success of the service. It is all well enough to require bids for this house or that, from the various contractors for the purpose of reducing the cost of wiring, fitting, etc., but the weak point heretofore has been not so strict specification requiring any special standard or systematic method of installation has been required. The consequence is that each contractor bids upon his own ideas of material, distribution and installation, the man performing the work for the least money generally being the successful competitor, which in many cases means, inferior material, poor workmanship and dissatisfaction. The insulation upon wires has been much improved in late years. In the early days of electric lighting wires were covered with cotton and coated with paraffine, much resembling our present bell wire, but this was found to be very inflammable, and in a short time it was replaced by a wire covered with cotton and white lead, and which is still known as Underwriter's wire, being then accepted by that body as a fire proof insulation and hence supposed to be safe. Later, however, it was found that it absorbed considerable moisture, causing leakage and fire by this means. "Protection against moisture meant prevention of fire," and accordingly our various rubber compound coverings made their appearance, and have developed into first-class but in some cases costly insulations. The tendency of the present time is not to place such expensive coverings upon wires, but to run them in conduits or tubes, which are lined with an insulating compound and covered with a metallic covering, protection from surrounding bodies being an insulation, as the word itself implies, bare wires of course being possible if entirely insolated. Wires were first run in tin or lead tubes, then cleated with wooden cleats or iron staples to girders, ceilings, walls, etc., in a promiscuous manner; later they were encased in wooden mouldings, or run upon porcelain insulators. Now, our standard wiring, from the points of safety, convenience, economy and, above all, accessibility, is undoubtedly the system of tubes or interior conduits. This is by far the safest and most reliable system, as a house can be tubed from top to bottom, with all necessary junction boxes impanneled in the walls, and the wires drawn through after the building has been completed, thus avoiding any broken wires, cut by nails or the plasterer's trowel. The advantages are many and obvious; the increased insulation or protection at a moderate expense, and the accessibility to all lines of repairs or removal, as one wire may be drawn from a tube and another readily inserted. The system of laying the tubes in a systematic manner is certainly a great advantage over the old way of running the wires in any direction, the rule generally being remembered that "a straight line is the shortest distance between two points," and, of course, requires the minimum amount of wire. The tubes are run in much the same manner as a line of gas or water pipes, and all forms of elbows, couplings, connectors, etc., are made for the various bends, turns, etc. With such a system the contractors are compelled to bid upon and furnish standard appliances and apparatus, the work is done in a more systematic manner and satisfaction and better service results. —*Electricity.*

PERSONAL.

Messrs. W. J. Borroughes and Joseph Wright, two representative plumbers of Toronto, were recent visitors to New-York.

Mr. Hamilton Killaly, C. E., who for many years was employed by the Dominion Government on the St. Lawrence canals, died a few days ago at Morrisburg, Ont.

The *Evangelical Churchman* pays the following tribute to the Christian worth of the late W. G. Storm: "It is not chiefly as a prominent and successful architect that we desire now to speak of him. It is rather as a Christian man. He was a member of the Church of the Redeemer, and at the time of his death was one of its lay delegates to the Synod. He took the deepest interest in all church matters. In his own church he was a zealous worker in connection with the St. Andrew's Brotherhood, and delighted in helping and encouraging his younger brethren to fight the good fight of faith. In that work his loss will be keenly felt. Mr. Storm was a strong advocate of temperance principles, and many a poor victim of the alcoholic temptation has found in him a sympathetic friend and helper. No one knows the amount of quiet good he has done in behalf of the helpless and needy. We extend our heartiest sympathy to his widow and family in their great affliction."

The Burlington Pressed Brick and Terra Cotta Company (limited), has been incorporated with a capital of $30,000.

HAMILTON

THERE is a fair amount of work going on here and prospects are rather encouraging. Messrs. Wood, Vallance & Co. will erect a large hardware ware-house at the corner of Hughson and King William Sts., under the direction of Architect Stewart.

There is some talk of putting up an office building on the corner of James and Main Sts., where at present there are some old wooden shanties which badly need pulling down. Architect Hills is putting up a weigh house at the John St. Market. Architect Balfour is going to put up a Grand Stand for the Hamilton Jocky Club to seat about 2,000 people, and also a Road and Club House.

The remodelling of the Grand Opera House is nearly completed. The accomodation will be largely increased, and for the amount of money expended the effect will be fairly good, but the carving is lifeless and too coarse. In some places where it is only a few feet from the spectator, it is coarse enough for the top of the building, and the faces of dramatic and musical celebrities are mere caricatures. It is a great mistake to introduce the human figure in carving unless it is going to be executed thoroughly well.

Mr. Geo. Tuckett's large residence on Queen St. is rapidly rising from the ground and looks very well; the carving, however, is so far disappointing; it has the common fault of being too coarse and lacks spirit. It is mostly in "Victorian Gothic" style with a little Italian Renaissance thrown in as it were, a rather incongruous medley!

Architect Mills is building a Sunday School for Zion Tabernacle at the corner of Pearl and Napier Sts., which is nearly completed.

There are a number of private residences being erected in all parts of the city.

CONDITIONS OF CONTRACT.

THE following conditions of contract have been adopted by the Queensland Institute of Architects and Queensland Builders, and Contractors' Association:

1. In the construction of these conditions and specifications, the singular number of the following words—namely, "employer," "contractor," "architect"—shall, where necessary, be taken to include the plural; the word "employer" shall mean the person or persons entering into the agreement with the "contractor"; the word "architect" shall mean the architect or firm of architects entrusted with supervision of the works.

2. The contractor, unless otherwise directed by the architect, is to provide all plant, scaffolding, tools, labour, and materials necessary for the due and proper execution of the several works included in this contract, according to the true intent and meaning of the drawings and specification taken together.

3. The architect during the progress of the works shall be the sole judge of all matters arising out of the contract, so far as relates to the quality of materials and workmanship, the interpretation and meaning of the plans and specification, the rate of progress, and the general management of the works; and against his decision, provided it be just and impartial, there shall be no appeal. Wherever the dimensions are written or printed upon the drawings, such dimensions shall be taken in preference to the measurement by scale. In the event of any discrepancy between the drawings and specification the architect is to decide which shall be followed.

4. The whole of the works comprised in this contract shall be executed with materials of approved quality of their several kinds, in the most substantial and workmanlike manner, and to the entire satisfaction of the architect.

5. All work and materials deposited on the ground, adjoining ground, or pathway by the contractor or by his order, for the purpose of forming part of the works, and on which an advance has been made, are to be considered the property of the employer, and the same are not to be removed or taken away by the contractor or any other person without the written consent of the architect. The employer is not to be in any way answerable for any loss or damage which may happen to any such work or materials, either by the same being lost or stolen or injured by weather or otherwise.

6. Should any workmanship not in accordance with plans and specification, or materials of improper or inferior description be introduced in any part of the works, the contractor shall, upon receiving the architect's written instructions, cause such workmanship or materials to be removed; and if the instructions so given shall not have been carried out within the time stated for that purpose, the architect may employ other persons to remove the objectionable workmanship or materials; and all expenses, loss, or damage thereby incurred shall be charged against the contractor, and be deducted from any money due or that may become due to him.

7. The architect shall have power from time to time, but only by an order in writing, to make any alteration, whether additions or deductions from the works as set forth in the accompanying drawings and specification. In the event of any such alterations being made, the contract shall not be vitiated, but the value thereof, if not previously agreed upon, shall be fairly and justly fixed by the architect in accordance with the schedule of prices annexed, if any, or where same may not apply, at fair measure and value In case of disagreement between the architect and contractor as to the value of such alteration, advantage may be taken of the "arbitration clause" hereinafter provided.

8. The building from the commencement of the works to the completion of same is to be under the contractor's charge; he will be held responsible for, and must make good all damages occasioned by any cause whatsoever, except such damages be caused by lightning, unusual floods, or earthquakes (provided such damage does not arise through any neglect of the contractor), and he is to hold his employer harmless from any claime for injuries to persons, or for damage to property through his neglect.

9. The contractor is to insure the building in an approved office, in the joint names of the employer and contractor, against loss or damage by fire, for the full amount of the contract, as soon as the building shall be covered in (or in the case of wooden buildings, as soon as the framework is erected), and must lodge with the architect the policies or "cover notes," and receipts for the premiums for such insurance. All money received under any such policies are to be applied in or towards the rebuilding or reparation of the works destroyed or injured. In case of neglect on the part of the contractor to insure, the employer may do so and deduct the amount of the premiums paid from any moneys due to the contractor.

10. The contractor shall not absent himself from the works without having a fully authorized and competent foreman or agent to act on his behalf. Any notice or order given to or served upon such foreman or agent, shall be considered as served upon the contractor, who will be held personally responsible for his proceedings and acts.

11. The contractor shall not sublet the work or any part thereof, without the permission of the architect. The architect may order the discharge of any workman for misconduct or incompetency, and such order shall be immediately acted upon by the contractor.

12. The contractor will be held liable for all violations of law caused by obstructing streets, side-walks, etc. He must give to the local authorities all requisite notices, and must obtain official licenses for hoarding enclosures, opening into common sewers, etc., and pay all proper and legal fees and charges. The contractor must keep up lights, etc., as required, construct proper enclosures, fences, and walks, for the protection and convenience of the public during the progress of the works. In case of any necessary excavation, the contractor must give due notice thereof to the proprietor of his agent, as also to the occupier of the immediately adjoining premises, and he will be bound to make good any damage that may be caused to such adjoining premises or buildings.

13. The contractor shall set out all the works comprised in this contract, but the employer shall survey and peg out the boundaries of the land on which the buildings are to be erected, and point out to the contractor prior to the commencement of the works all such surveys, boundaries and pegs.

14. Should the contractor not commence operations within seven days after the date of signing the contract, or should it at any time appear to the architect that there are not sufficient workmen engaged upon the works, or that there is not sufficient material upon the ground to enable the works to be completed by the specified time, the contractor shall, within 48 hours after receiving notice in writing from the architect, commence operations, or cause such number of competent workmen to be employed, or such quantity of material to be placed upon the site as he may direct. Should the contractor refuse or neglect to commence operations, or to employ such additional workmen, or to place such quantity of material on the site, or at any time during the progress of the works refuse or decline to execute anything set forth in the drawings and specification, or that may be ordered by the architect as necessary for the proper execution of the works, the employer, by the architect, may, after giving three days notice to the contractor, take possession of the works and adopt such means as may seem best for the completion thereof. The costs so incurred in finishing the works with all charges for overtime shall be borne and paid by the contractor, and shall be deducted from any moneys due, or that may become due to him.

15. If the contractor shall become bankrupt, or compound with or make any assignment for the benefit of his creditors, or shall suspend or delay the performance of his part of the contract, the employer, by the architect, may give to the contractor or his sureties, or assignee, or trustee as the case may be, notice requiring the works to be proceeded with, and in case of default on part of the contractor, or his sureties, or assignee, or trustee, for a period of — days, it shall be lawful for the employer, by the architect to enter upon and take possession of the works, and to employ any other person or persons to carry on and complete the same, and to authorize him or them to use the plant, materials, and property of the contractor upon the works, and the cost and charges incurred in any way in carrying on and completing the said works are to be paid to the employer by the contractor, or may be set

off by the employer against any money due, or that may become due to the contractor.

16. The contractor is to complete and deliver up the whole works which are included in this contract on or before the——day of——; in default thereof he shall become liable for the sum of —— per —— for each and every ——that the work remains unfinished or undelivered after the said——day of——provided that possession of the premises be given the contractor, and lines and levels of the building furnished him, within——days of the acceptance of tender. All such sums to be deducted from the balance due and charged as by the way of liquidated and ascertained damages for delay of the works, or for cause of damages as per clause 8, and not as a penalty. Reasonable allowance in the time for completion of contract shall be made for delay of works on account of bad weather, legal holidays, and strikes amongst the workmen employed.

17. Payment shall be made to the contractor at intervals during the progress of the work, as follows—viz., upon the certificate of the architect, at the rate of——per cent. upon the value of the work actually executed. The remaining——per cent. shall be paid after the architect has certified that the contractor has executed and completed the work to his satisfaction, except a sum equal to 2½ per cent. on the total amount of the contract, which shall be retained for a period of——weeks from the date of the last or final certificate in order to ensure the execution of any reinstating of improper or defective work that may be required by the architect during the above period; such reinstating shall be performed to the satisfaction of the architect before the contractor shall be entitled to receive the said balance of 2½ per cent. No payment whatsoever, whether progressive or final, will be made except upon the certificate of the architect.

18. No progressive certificate is to cover or relieve the contractor from his liability under the provisions of clause No. 6, whether or not the same be certified by the architect at the time of or subsequently to granting any such certificate.

19. The certificates for payment of instalments are to be payable at sight by the employer, and the contractor shall, in addition to his right of his immediate action on nonpayment of any such certificates, have also the following rights and remedies:

1. If the employer shall make default in paying any moneys to which the contractor may become entitled for seven days after the certificate of the architect has been presented to the employer for payment; or

2. If the work be delayed 28 days for or by reason of or under any legal proceedings taken by any other parties and not being caused by the neglect, default, or laches of the contractor, or seeking any remedy or claiming injunction in consequence of any neglect, default, or laches of the contractor, the contractor is to be at liberty at his option to suspend the works, and to require payment for all works executed, and all materials wrought up, and for any loss which he may have sustained upon any goods or materials purchased for the works, and in such case the contractor is not to be bound to proceed further with the works contracted for. The contractor is to be entitled to bank interest upon all moneys payable to him, payment of which may have been unduly delayed.

20. All drawings and papers whatever supplied by the architect, are to be kept by the contractor on the works; and the contractor hereby undertakes not unnecessarily to expose or use them for any other purpose whatever than that for which they are held in trust by him—viz., the execution of the works contracted for; and, further, that he will, upon receiving his final certificate, return all such drawings and papers to the architect.

21. In case any dispute shall arise between the employer, or the architect on his behalf, and the contractor touching the value of any alterations, additions, or deductions, as referred to in clause 7, or as to sums to be deducted as liquidated damages for overtime, see clause 16, or as to cause of damages to works referred to under clause 8, the dispute shall be referred to the decision of two arbitrators, one of whom shall be a fellow of the Queensland Institute of Architects, and the other a member of the Builders and Contractors' Association of Queensland, with power to appoint an umpire. The decision of any two of the arbitrators, or of the umpire, shall be final and binding upon all parties concerned, and from it there shall be no appeal. The award is to be made within seven days, or such extended period as the arbitrators may decide upon from the date of submission, and it shall direct by whom and in what proportion the costs of such arbitration shall be paid.

22. In case the contractor or employer should neglect to appoint an arbitrator within one calendar month next after a request duly made, or after the time specified for the appointment of the arbitrators and determination of the matter as aforesaid, the employer or the contractor, as the case may be, may appoint an arbitrator on behalf of the other party, and the arbitrator so appointed shall have the same powers and authorities as if he had been appointed by the contractor or the employer, as the case may be. Forthwith upon the appointment of the arbitrators they shall proceed to hear and determine the matter so referred to arbitration.

23. This submission to reference, and the award thereon, shall become a rule of the Supreme Court of Queensland on the application of either party to this contract.

These are conditions referred to in the annexed agreement, made on the ——day of——between the undersigned for——

In the presence of——

The Toronto Pressed Brick Co, the Ontario Terra Cotta and Brick Co., and Messrs. Taylor Bros., of Toronto, had each a very creditable exhibit at the Industrial Fair. The last mentioned Company also exhibited samples of glazed bricks in various colors of their own manufacture.

MANUFACTURES AND MATERIALS

POROUS TERRA COTTA.

Terra cotta for fireproofing does not appear to be as extensively used in England as has been the case here, observes *Architecture and Building*. We note that special mention is made of an experiment made last month at Bishop's Waltham Hants. The experiment was made in a little building of the dimensions of one room of an ordinary house, with brick sides and a terra cotta floor above, the pieces being so dovetailed as to render it almost hermetically sealed. The floor was reached by means of a wide stair case, with an ornamental balustrade, resembling that of carved oak. In the room below faggots of wood were piled up to the ceiling. Round these at the bottom were placed tar barrels, with a layer of straw. The mass was set on fire and the fire burnt with great intensity. While this was going on most of the visitors ascended the staircase and stood on the floor, feeling the slabs from time to time to see if the heat was making any impression on them, but throughout the whole trial they maintained almost the same temperature, being quite cold. By-and by the fierce flames lapped themselves round the staircase, cutting off retreat by that way, and had it been constructed of wood short work would have been made of it. However, beyond being slightly blackened with smoke, it remained as impassive as the floor above. The room was one mass of white heat, resembling in color molten lead. Had the floor fallen in at that time cremation would have been the fate of those in it. The party remained on the roof from half to three quarters of an hour a sufficient period to put the experiment to the severest test and so little had they felt the heat below that many shivered with cold. Immediately the visitors descended, a large number of the workmen and boys ran up the stairs and jumped about on the floor, which apparently had not in any way been affected by the great heat, though the fire continued to burn for a considerable time afterward. This porous terra cotta fire proofing material, which is being extensively manufactured at Deseronto, Ont., has gone largely into use in the erection of important buildings in Montreal and Toronto, during the last three years. It may be used to equal advantage in connection with brick, stone or wooden construction.

QUALITY OF BRICK.

Three main points with reference to brick have to be taken into account, says *The Brickmaker*. 1, The power of resistance under pressure; 2, the appearance of the fracture, which should present an even texture, and a fine brilliant grain, without cavities in the interior, and neither ribbony nor stony; 3, the exterior, which should be smooth and regular, the angles and edges sharp and straight. When the size of the brick is equal throughout the mass it is a proof that the brick earth has been well prepared and the brick generally well made. A brick, when struck, should give forth a clear, ringing sound. Good brick are generally of a dark reddish brown color, and sometimes they show vitrified spots on the surface; it is not well, however, to depend too much on the last fact, for it is often only an indication of the amount of heat to which the brick has been subjected, while the clay of which the brick is made may be impure and ill prepared.

Bad brick are readily recognized by their reddish yellow color, but still more by the dull sound which they emit when struck; their grain being soft, they crumble easily and absorb water with avidity. A good brick should not absorb more than one fifteenth of its own weight of water; it should appear and, in reality, be dry. A brick that does not take up any water at all is too much burnt; the mortar adheres to it imperfectly, but is a good conductor of heat. Such brick may be used in damp soil and for pavements. When a brick left in water, either scales or swells, it is of bad quality and contains caustic lime. A brick which being made red hot, and then having water poured on it, does not crack, is of extraordinary and rare quality, and those which have borne the effect of moisture and dryness during two or three winters without scaling or cracking, are excellent.

In order to try if brick will bear the effect of frost, let one be boiled for half an hour in a solution of sulphate of soda saturated cold, and then suspended by a string over the vessel in which it has been boiled. In twenty-four hours the surface of the brick will be covered with small crystals; the brick is then to be immersed again in solution until the crystals disappear, and again suspended; repeating this operation for five days, the crystals reforming after each immersion. If after this treatment a number of particles of the brick are found at the bottom of the vessel containing the solution, the brick are incapable of withstanding the effects of frost.

IMPORTED VS. AMERICAN CEMENTS.

Sackville, N. B., August 25th, 1892.

Editor Canadian Architect and Builder.

Sir,—I sincerely trust that the Government will not impose a higher duty on imported English cement; at present it is protected by a duty of 40 cents per barrel. The statement published by you of the failure and deterioration by age of Portland cement is not in accord with my 40 years experience. I have the statement of a very reliable firm of cement manufacturers, that buildings erected with their cement have been subjected to great wear and tear for more than 80 years and are still intact. The cement manufactured by this firm was used in the following lighthouses (as a rule a lighthouse is more exposed to the action of the sea and atmosphere than perhaps any other class of work): The new Eddystone, Bishop's Rock, Watling Island, The Sombrero, St. Catherines, The Minicoy (China), Dondra Head, The Welmadhwa, Ceylon, and no complaints of the failure of the cement have ever reached the manufacturer.

I have had American cement signally fail, putting me to great expense and inconvenience. I certainly will not try it again, at the head of the Bay of Fundy at least.

Yours truly,

Rich C. Boxall, C. E.

SANITATION, HEATING, LIGHTING

ELECTRIC HEATING.

Some interesting and successful experiments in the line of heating by electricity have been in progress at Ottawa, Ont., for nearly a year past. The apparatus employed is the invention of Mr. Ahearn, general manager of the Ottawa Electric Street Railway. We reproduce from the *Western Electrician*, the following particulars and illustrations of the apparatus:

A cross-section of the electric boiler for car heating is shown in detail in Fig. 1. It consists of a shell or tube 2 of oval cross-section, within which is placed another similar but smaller shell

Fig. 1.

3, the two having their ends suitably joined to form a water space between them, nozzles being provided for the circulating pipes. The vessel thus formed has its exterior surfaces insulated with strips of asbestos 4. A core, 5, also insulated with strips of asbestos, and wound with a resistance coil R of German silver inserted in the inner vacant space of the shell 3, and is of such a size as to press the wires R against the insulation of the shell 3. A similar resistance coil R is also wound upon the insulated shell 2, the terminals of the coils projecting. The vessel thus formed is placed in a casing 6, the terminals of the coils passing through insulators, and all the vacant spaces inside the casing being filled with powdered whiting. This casing is then wrapped in sheets of asbestos and inclosed in a wooden box secured to the under side of the car floor. Two of the boilers are used in each car, being placed in diagonally opposite corners, each supplying a set of circulating pipes. The resistance coils are placed within the car circuit. The nozzle in the upper side of the boiler

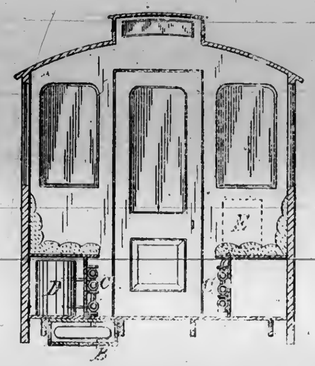

Fig. 2.

is connected with an upright supply pipe; from this the radiating pipes C branch off, running to the other end of the car, where they are connected with another upright pipe. From this last mentioned upright pipe a return pipe passes through the floor and enters the boiler by the lower nozzle. A water reservoir D is placed under the seat and communicates with the flow and return pipes to keep the circulating pipes full of water and to compensate for evaporation. An expansion tank E is placed at the end, away from the boiler, one in each set of pipes. This tank being high and flat, is concealed in the end panel of the car, and it provides for the variations in the level of the car and the water.

The liquid heater shown in Fig. 3 was next devised. This heater is of handsome design, with a water glass on its side showing the height of the water within it. This type is wound for all voltages, and has, it is stated, been used for the last three months with most satisfactory results by patrons of the Chaudiere Electric Light Company of Ottawa, which company uses the Westinghouse alternating system. These heaters are used by barbers, druggists and for domestic purposes. A livery stable keeper uses a three gallon heater, the hot water being

Fig. 3.

Fig. 4.

applied to clean harness and bathe horses' feet. The heater shown in Fig. 3 requires 3½ amperes at 50 volts. Such is its construction that when in use in barber shops the water in it is found sufficiently hot for shaving in the morning, although the current has been off all night.

In March last Mr. Ahearn had constructed and put in operation in the residence of ex-Alderman Johnstone the electric furnace shown in Fig. 5. This outfit has been in successful and and continuous operation since being installed, and has attracted much attention. The large coal furnace abandoned for the small perpendicular electric furnace shown in Fig. 5 suggests immense possibilities for electric heating. The heated water passes upward into the 63 gallon tank in the corner, from which it flows to the two upper stories of Mr. Johnstone's residence, supplying three bathrooms and one kitchen sink. The fact that

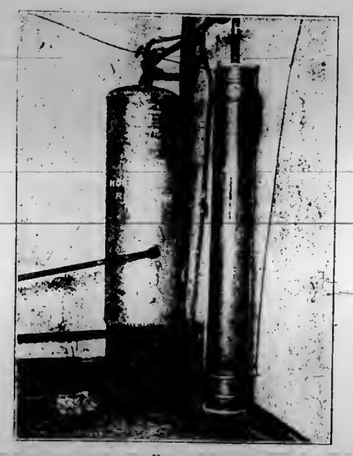

Fig. 5.

hot water is being constantly drawn off, and cold water taking its place, is a much more severe test upon the furnace than if the water was being used for heating purposes only, as in the latter case the water is being circulated always. Mr. Ahearn has applied this principle to the hot water apparatus employed for car heating.

Mr. Ahearn, proposes this year to equip all the cars, the car shops and the new power house, with his new system of electric hot water heating. He has also arranged with C. F. Sise,

president of the Bell Telephone company of Canada, to heat the new telephone building now being erected in Ottawa. This installation alone will require 6,000 feet of pipe. For this undertaking the 50 volt alternating current will be used.

THE SANITARY CONDITION OF TORONTO.

THE pollution of Toronto Bay by sewage, the filthy condition of Ashbridge's Bay, and the existence of twelve thousand privy pits within the municipal boundaries, have been a standing menace to the health of the citizens of Toronto for several years past. From the Local and Provincial Boards of Health, the medical profession, and citizens having at heart the city's welfare, have come to the Council repeated and urgent requests for the removal of these nuisances. Typhoid and diphtheria have been unusually prevalent of late, and notwithstanding there was the possibility of cholera reaching this country, a deaf ear was turned to the appeals for sanitary improvement. Now that cholera has actually found its way almost to our doors, the insanitary state of the city invites it to take up its abode and carry on its dreadful work in our midst. In view of the near approach of cold weather, there is a probability that the disease may not attack the city for some months. Advantage should be taken of this period to rid the bay of its foul contents and construct an intercepting sewer along the water front to discharge the sewage at a safe distance from the city. The privy pits, which are undoubtedly the source of most danger, should be closed up as fast as possible, and pending their extinction, should be cleaned at frequent intervals. The city's finances have been largely drawn upon of late for public improvements, but no false economy should be permitted to stand in the way of whatever expenditure may be required to guard the public health.

WATER AND WASTE PIPES.

THE leakage of water pipes behind decorated walls and in fine ceilings is a sufficient argument against casing or covering service-pipes. The repairs are generally costly in themselves; and they entail the additional services of the carpenter and decorator, as well as those of the plumber. Pipes in casings, or set in walls or partitions, as they pass from floor to floor, provide especially inviting runaways for mice, rats and vermin of all kinds. Nests are built in these places; scraps of paper, rags and food are carried into them, and they become filthy. It is only necessary to remove a covering board from almost any casing to prove this point in a most convincing manner. Even those in comparatively new buildings will be found surprisingly foul.

These casings, recesses or wall-pockets, as the case may be, serve another and usually very unexpected purpose. They act as ventilators, and distribute odors from the kitchen and cellar to all parts of the building. In the performance of this duty they are faithful and impartial. The hollow walls and floors which are nearly universal in the American system of construction greatly assist in this work. Many of the fine French flats which were first erected in the city of New York are now rented with difficulty, owing to the odors which prevade them. When shut up for a short time they are almost unbearable. Rents have of necessity been reduced to one-third the original figures, from this reason alone. The cause is usually found in the careless and ignorant arrangement of pipes and their cases. The odors from the kitchens are carried everywhere. Stale odors from closets and from food from kitchens and garbage-boxes are mingled and distributed with perfect fairness to all the occupants. The large air-shafts, usually held responsible for this state of things, have very little to do with it. The casings open at the ceiling of each kitchen, communicate with all the floor and wall spaces, and usually take their supply of odors from a point very near the range. All of them are directly connected with the cellar, and usually start in some way from the janitor's kitchen.

Numberless complaints coming from new flats of sewer-gas are finally traced to the odors of cabbage, turnips, ham, onions, etc., which have come from the janitor's kitchen. In many buildings this kitchen is directly under the parlor of the first-floor apartment, and is separated from it by one thickness of boards and an inch of plastering. That there should be foul smells on the first floor is not to be wondered at. Tests of the plumbing in these cases are made, and its profection proved.

There is nothing to be said upon the other side of the question. There are no good reasons for putting pipes out of sight. When people say, in the face of these facts, that they can't bear the suggestiveness of having the pipes where they are visible, they make an acknowledgement that they prefer hidden filth, danger to life, health and property, to a right construction. Life and health cannot induce them to accept and frankly tolerate their plumbing work.

Pipes carried openly through a building are not dangerous because their condition can be constantly observed. If accidents occur, the point at which the break takes place can be reached at once and repairs easily made. The quality of the work gains materially, because the plumber takes pride in putting up work which is to be exposed. He has a natural and very justifiable pride in having the workmanship creditable to himself. This pride is increased by certain traditions of the trade, and there is a double gain to owner and occupant.

Exposed pipes may be made to pass through floors without leaving an an opening. The floor around the pipe can be made perfectly tight, and the passage of odors cut off completely—at least, as perfectly as the nature of plaster will permit. This is an enormous gain, while the runaways for rats and mice, roaches and water-bugs, are entirely done away with. These vermin can then be exterminated. This is practically an impossibility in houses where casings protect them and afford perfect breeding-places. Cut off from free passage to all parts of the houses, they prefer more congenial quarters, where rapid transit and fields for colonization are provided.

As decorative features of the rooms, cast-iron pipes at least are often treated in a beautiful way. The body of the pipe is colored a very dark-bluish gray, scarcely removed from black. The bands are silver or nickel bronzed, or have silver or nickel leaf applied to them. Occasionally the whole pipe is finished with two or three shades of bronze. Lead and wrought-iron pipe receive somewhat similar treatment. The lead is often polished and varnished. There is, however, no difficulty in making the decoration of the pipes strikingly effective.

It is satisfactory to know that architects and builders are beginning to break away from the old custom, and expose their pipes wherever the prejudices of the owners can be overcome. Some of the best men in the profession are treating the plumbing work in a manner to show constructively its importance and value. The result is a great gain both to owner and occupant.—*Mechanical News.*

BRASS FOR DECORATIVE PURPOSES.

THE toughness of brass, allowing of economy of material in its use, so securing lightness of construction, together with its brilliant, enlivening appearance, has maintained it in constant favour for various articles of household furniture, while in chased, engraved and repoussé designs, cut open work and in the round, hammered or cast, it has become an important factor in interior decoration, the more so that it tends to harmonize neighbouring colors, as well as to form effective contrasts with hard woods, whether light or dark.

Its scope has been enlarged by the variety of tints given to it by certain superadded elements in the fusion of copper and zinc. Among these are golden orange, greyish green, violet moiré, olive and olive green, and brownish and reddish hues of different intensities, to which is to be added the effect of fire gliding, the peculiar lustre occasioned by which is altogether different from that resulting from the mere application of gold leaf to a metallic or other surface.

Decorative devices include antique or fanciful or ideal figures—human, animal or legendary—masques, flowering plants, arabesques, scrap and scroll work. In furniture, brass is utilised for tables or their supports, fire screen frames, chandeliers, candelabras, brackets, lamps, picture and mirror frames, fire dogs, cabinet mountings and so forth. Key plates, handles of doors, central ornaments and corner pieces for panels, usually in cast relief or incised ornament, are included in the general uses to which it is put. Decorative brass requires for its best effect prooounced designs free from complexity. Objects from nature when represented in this metal are commonly conventionalised selections being made of prominent characteristics.

The Italian preference for carving and sculpture over working in metals left brass in abeyance in the period of Italian Renaissance, but it was otherwise in that splendid outburst of artistic power, the French Renaissance, when this metal obtained full recognition.—*Furniture and Decoration.*

QUERIES AND ANSWERS.

A TORONTO subscriber writes: Upon taking down a building on King Street, I discovered a crack in the wall of the adjoining building, which, if subjected to a slight jar, would probably be the means of precipitating the front of the building into the street. This defective wall was in no way supported by the building which was taken down. I would like to know whether, under the law, any responsibility attaches to me by reason of my having caused the removal of the building to which I have referred?

ANS.—The law provides that you should give the adjoining owner six months' notice of your intention to remove the building. In default of such notice, you are liable for any accident which may occur to the defective building.

An increase of $107,231 is shown in the value of new buildings erected in Hamilon the present year as compared with 1891.

CANADIAN ARCHITECT AND BUILDER.

VOL. V.—NO. X. TORONTO AND MONTREAL, CANADA, OCTOBER, 1892. PRICE 20 CENTS / $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),
PUBLISHED ON THE THIRD SATURDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.
C. H. MORTIMER, Publisher,
14 King Street West, - TORONTO, CANADA.
64 TEMPLE BUILDING, MONTREAL.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1892.

PRESIDENT	S. G. CURRY, Toronto.
1ST VICE-PRESIDENT	KING ARNOLDI, Ottawa.
2ND VICE-PRESIDENT	F. J. RASTRICK, Hamilton
TREASURER	D. B. DICK, Toronto.

COUNCIL:

WM. G. STORM	Toronto.
DAVID EWART	Ottawa.

JAS. CRANG.
M. MURPHY.
J. LISTER NICHOLS.
WM. PEARS.

JOHN L. PHILLIPS, Secretary.

THE next convention of the American Institute of Architects will take place at Chicago on the 20th and 21st inst., coincident with the inaugural exercises of the World's Columbian Exposition.

THE demands upon our space this month preclude the publication in this number of more than one of the instructive papers read at the recent convention of the Province of Quebec Association of Architects. We hope to be able to present the others in our November number.

THE architects of the Province of Quebec are complaining of the action of the Provincial Government in imposing upon them a professional tax, thus placing them on the same footing as lawyers and doctors, while at the same time refusing to their Association the rights and privileges accorded to the other professions. They rightly object to being recognized as a profession for taxation purposes only.

THE concrete floors in the new Royal Victoria Hospital, Montreal, although as yet subject to no wear, are full of holes, and will probably have to be replaced by something more substantial, such as granolithic. The difficulty appears to be that the concrete is too rich, and the layer is of two great depth. A very coarse grade of sand is required to make good concrete, and this cannot be obtained in the vicinity of Montreal.

THE burden of taxation imposed upon manufacturers, resulted a few years ago in the removal of a number of factories from Toronto to suburban towns and villages. One of the greatest needs of the city to-day is a greater number of manufacturing industries affording employment to the artisan class. It is hoped that the by-law under which manufacturing plant will hereafter be exempt from taxation, will induce manufacturers to locate in a city which has many other advantages to offer.

THE severity of the climate in winter in the Province of Quebec, calls for certain distinctive requirements in the construction of buildings, especially residences, to ensure the stability of the structures and the comfort of the inmates. For example, a double roof has been found to be an essential in house construction. With a single roof, the snow, which there falls in such abundance, would melt and cover the roof and sides of the house with ice. To avoid this, the roof is made double, with an air space between. Thus the upper roof receives no warmth, and the snow usually, crisp and dry, instead of being melted, is constantly blown away by the wind.

SEPTEMBER 30th was the date set for the close of the preliminary competition for designs for new the public buildings which are proposed to be erected at Victoria, B. C. All the designs received will be submitted to two non-competing architects, who, in conjunction with the Chief Commissioner of Lands and Works, will advise which five designs shall be selected for a final competition, and in the final competition, which design, in their opinion, should be placed first, the author of which will then be entrusted with such portions of the works as the government may decide to proceed with, on the usual terms. The authors of the five designs selected for the final competition will be paid an honorarium each of $750. The cost of the building must not exceed within ten per cent., the sum of $500,000.

SEVERAL boiler explosions, attended with disasterous results to property and human life, have recently taken place in various parts of Canada. The most recent accident of this nature occurred a few days ago in the basement of one of the large business buildings in Hamilton. One of the large boilers used for heating the building exploded, wrecking a second boiler and setting fire to the premises. The fire department fortunately succeeded in putting the fire out. The boiler must have exploded under a very low pressure of steam, otherwise the results would certainly have been more serious. Occurrences of this kind emphasize the need for a higher standard of proficiency on the part of persons entrusted with the care of steam plants. Steam boilers in the hands of incompetent persons are almost

as dangerous in the basements of buildings as a package of dynamite. The law should require persons who aspire to take charge of steam boilers to show by examination that they possess the knowledge which would qualify them for the position, and a penalty should be imposed on persons assuming the duties of such a position without having undergone examination. Unless some provision is made which will insure competency, we may expect to hear of disasters even greater than those which have already occurred.

THE class of persons who regard architects as the possessors of but little knowledge that is not shared by the public at large, and their services as being of trifling value, while steadily diminishing, is by no means extinct, even in our cities. While few persons can be found who consider themselves competent to be their own physician in case of serious illness, and few also who would undertake to act as their own lawyer in a case involving important interests, there may yet be found any number who believe themselves competent to be their own architect, and who with the object of saving architects' fees, will undertake to plan and superintend the erection of buildings in which thousands of dollars of their capital is to be invested. It is scarcely necessary to say that such attempts almost invariably result in expensive blundering and life-long regret; notwithstanding, there can usually be found somebody else prepared to repeat the experiment. Our attention was drawn to a case of this kind the other day. A well-to-do resident of a Canadian city decided upon erecting a residence in keeping with his position, and having ideas of his own on the subject, concluded to be his own architect. Accordingly he drew up a plan to his liking, and set men to work to take out the excavation and build the foundation walls. At the completion of this stage of the work, he found himself confronted by difficulties which he had not foreseen, and which his want of knowledge made it impossible for him to overcome. In this extremity he found his way to an architect's office, and asked to be assisted out of the dilemma in which his conceit had placed him. On examining his client's drawing, the architect found a cellar with a twelve foot ceiling, a chimney with a flue less than half the size required to carry off the smoke from the furnace, and other defects equally glaring. After much thought the architect succeeded in bringing order of chaos, and it is safe to say that the number of those who think they know all about architecture has been reduced by one.

THE third annual convention of the Province of Quebec Association of Architects, to a report of the proceedings of which much space is devoted in this number, was in some particulars the most successful which has been held since the inception of the organization. It included an exhibition of drawings which was a source of much interest, and which it is hoped will be made an important feature of future meetings. For the first time the members had the pleasure of listening to a number of instructive papers contributed by members of the Association. The visit of inspection to various public buildings recently completed and in course of erection was a feature of the occasion which proved to be full of enjoyment and profit to every one who participated. The banquet afforded opportunity for the expression of some thoughtful remarks regarding the Association's past history and future aims. In these particulars the convention was a gratifying success. In point of attendance, it was somewhat disappointing. A large number of the architects of the city who are members of the Association were conspicuous by their absence. We regret to have to record this fact, which reveals an apathy on the part of the Absentees concerning the welfare of the association which must prove a serious hindrance to its progress. It is a pleasure to know, however, that a considerable number of the members are earnestly desirous of assisting by every means in their power to place the organization in the position to accomplish the objects for which it was called into existence. Much has already been accomplished, and a work of incalculable advantage may be done if every member will resolve to faithfully discharge his responsibility, even though he may be obliged to do so at the cost of some personal sacrifice. At future meetings the opportunity for a profitable discussion upon the papers presented, should be afforded, as in this way information of great value may be elicited. The Association enters upon the new year under the guidance of an efficient staff of officers, and should at the close of the current year, be able to show a marked advance in the direction of its ultimate goal. We hope to see the classes for students revived at an early date, and the students and members of the Association heartily co-operating to make them of the greatest possible interest and value.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

THE third annual convention of the Association was held in the Association rooms, St. James Street, Montreal, on Thursday and Friday, Sept. 29th and 30th.

The President, Mr. F. X. Berlinquet, of Quebec, presided at the first session, which opened at 10 o'clock.

The following members were in attendance:

F. X. Berlinquet, President, in the chair; J. Nelson, first Vice-President; A. F. Dunlop, D. Ouellet, A. T. Taylor, V. Roy, J. F. Peachey, H. Stavely, A. Gendron, S. Lesage, C. Baillairgé, J. J. Browne, J. Z. Resther, H. C. Nelson, J. R. Rhind, A. Boileau, A. Raza, E. Mann, J. Perrault, M. Perrault, H. M. Perrault, A. C. Hutchison, L. Z. Gauthier, J. Venne, and G. Languedoc.

An interesting collection of architectural drawings adorned the walls. The list of subjects and exhibitors is as follows:

Eric Mann—"Evans Buildings, Montreal"; "Design for Scotch, Baronial Mansion."

Perrault & Mesnard—"Longueuil Church"; Monument Nationale, Montreal"; "Laval University."

A. C. Hutchison—"Sketch for Church"; "Design for Bank"; "High School Building, Montreal"; "Sketch of Mantel."

J. J. Browne—"Presbyterian College, Montreal"; "Residence, St. John, N. B."; Stormont Cotton Mill"; "Monument, Montreal"; "Design for Fraser Buildings."

A. T. Taylor—"Second Premiated Design for Municipal Buildings, Glasgow"; "Physics Buildings, McGill College"; "McDonald Buildings, McGill College"; "Montreal Branch Bank Building, Montreal."

Wright & Son—"Design for Bank, Montreal"; "Residence, Dorchester Street, Montreal."

A. F. Dunlop—"Temple Building, Montreal"; "St. James Methodist Church"; "Dunlop of Dunlop, Ayrshire, Scotland"; "Residence, Dorchester Street, Montreal."

J. Nelson & Son—"Design for Lennoxville College."

F. X. Berlinquet—"Interior of Beauport Church."

Jos. E. Huot—"Church, St. Anne de Beaupre."

Jos. Venne—"Front elevation of Church."

J. C. A. Heriot—"Design for City Front"; "Design for Residence"; "Design for Country House."

D. Ouellet—"Exterior and Interior of St. Joseph's Church, Quebec."

J. W. & E. C. Hopkins "Merchants' Bank, Montreal"; "Warehouse, Craig Street, for J. C. Wilson"; "Interior of Church, Dublin."

J. F. Peachy "Interior St. John's Church, Quebec"; "Design for Post Office, Quebec."

C. Baillairgé—"Interior of Church"; "Monument Aux Braves."

After a few prefatory remarks by the President, Mr. Roy rose to complain of defects in translation in the newly printed copies of the constitution and by-laws. To prevent the recurrence of such defects in future, he suggested that the Association should appoint a Secretary who understood both languages, and mentioned the name of a gentleman who would suitably fill the position. The officers had done everything in their power for the success of the Association, and if the defect mentioned were remedied, the success of the Association for the coming year would be insured.

The minutes of the annual meeting held in Quebec on the tenth day of September, 1891, were read and confirmed.

The following report of the Council was submitted and re-read in French and English:

Your Council since the annual meeting held in Quebec on the tenth day September, 1891, held ten regular and seven special meetings, the attendance being as follows: A. C. Hutchison, 17; W. E. Doran, 13; A. T. Taylor, 12; V. Roy, 11; J. Nelson, 11; A. Raza, 11; A. F. Dunlop, 11; C. Clift, 6; F. X. Berlinquet, 5; J. F. Peachy, 3; M. Perrault, ; J. J. Browne, 1.

At the first meeting of the Council held after the last annual meeting, a committee of two was appointed to consider the question of building inspection in this province and to report. After some time one member of the committee unable to obtain a meeting with his colleagues, submitted a report giving his views as to the lines on which laws regulating building should be framed and suggesting the appointment of another committee to more fully consider the matter. The Council, owing to the difficulty of getting members who could give the time necessary to serve on this committee, have not been able to reappoint it.

Messrs. Berlinquet and Baillairgé, of Quebec, and Messrs. V. Roy, W. T. Thomas and A. T. Taylor, were appointed as a Board of Examiners. Previous to the semi-annual examination held in Montreal in the month of July, two vacancies occurred in the Board; one by the resignation of Mr. V. Roy, and the other by the decease of Mr. W. T. Thomas. The vacancies were filled by the appointment of Messrs. J. Haynes and A. C. Hutchison.

Two examinations were held during the year: one in Quebec in January, and the other in Montreal in July. At the former, one candidate, Mr. Remi Lemay presented himself for final examination; having successfully passed it, his name was entered on the register. At the examination held in Montreal six candidates presented themselves for the preliminary examination to enable them to enter upon the study of Architecture. Four of the candidates succeeded in passing the examinations.

In the month of May last, Mr. C. Clift tendered his resignation as Secretary. The Council regretted having to accept of it in view of the valuable services he had rendered the Association in its inception and formation.

Mr. A. C. Hutchison, a member of the Council, was appointed Secretary, and the vacancy thus caused in the Council was filled by the appointment of Mr. J. J. Browne.

Early last fall the Council, with a view of bringing the members of the Association together at frequent intervals for mutual improvement and interchange of opinions, arranged for monthly meetings at which papers of interest to the profession would be read and discussed. Papers were prepared

and read by Messrs. Hutchison, Doran and Haynes. The Council regret that the opportunities thus afforded the members for meeting together were not taken as full advantage of as they might have been, but hope that the new Council will afford such opportunities during the ensuing year, that the members will take full advantage of them.

With a view to afford student associaties opportunities of advancing their studies in Architecture, lectures were delivered weekly for three months on the styles of Architecture, and a class for the study of pen and ink drawing was formed. These lectures and classes were not as largely attended as was expected, but as the formation of these classes last winter was somewhat of an experiment, the Council hope that if the lectures and classes are continued during the ensuing winter months, that students will fully appreciate the facilities of study thus afforded them.

The Council regret the delay that has taken place in the printing of the By-laws and Act of Incorporation, but as a copy has now been furnished to each member, the want of them which may have been felt has been removed.

The tariff of professional charges and practice prepared by the preceding Council in conformity with the Act and presented to His Honor the Lieutenant Governor in Council for ratification was, owing to the change which took place in the Government of the Province last February, left in abeyance, and as your Council did not consider the time opportune to present it to the new Government immediately after their accession to office, they did not do so until after the close of the session; in the meantime another clause was added fixing the charge for valuations of property. The tariff as amended was laid before the Government on the first opportunity that presented itself, and its ratification was personally requested by the members of the Council who waited upon the members of the cabinet. Since then a correspondence has taken place with the Honorable Provincial Secretary respecting the tariff of charges and professional practice of architects in the United States and in Europe, and it is hoped that a confirmation of our tariff will soon be reached.

During the last session of the Legislature a Bill was introduced providing for the granting of certain privileges to contractors, architects, workmen, and parties furnishing materials for building. As the privileges to architects provided for in the Bill had not been asked for, and are considered unnecessary by the Council, several members of the Government were communicated with and requested to prevent the Bill from becoming law; it was, however, withdrawn, before discussion upon it took place.

When the office of Sanitary Inspector became vacant by the decease of the late occupant, your Council addressed the city council requesting them to make the salary attached to the office sufficient to secure the services of a thoroughly competent sanitary engineer, and to only appoint one who was thoroughly qualified.

In response to an invitation from the Ontario Association of Architects to attend their annual meeting and dinner last February, Messrs. Clift and Hutchison on behalf of the Council attended and conveyed its greetings.

During the last session of the Dominion Parliament a deputation from the Ontario Association waited upon the Government to urge upon them the enforcement of the Customs Tariff on plans prepared in the United States and sent into Canada. Your Council appointed a deputation to support the Ontario Association in bringing the matter before the Government.

Your Council regret to record the decease of two members of the Association since our last annual meeting, namely Mr. W. T. Thomas, in June, and Mr. W. H. Hodson, last week. Resolutions of regret and condolence were passed by the Council and entered upon its minutes.

The whole respectfully submitted on behalf of the council.

The Treasurer's statement was submitted showing the gross receipts for the year to have been $1245.53 and the expenditure $1028.11 leaving a balance on hand of $217.42. Accompanying the Treasurer's statement was the Auditors' report, stating that they had examined the accounts and found them correct.

It was moved by S. Lesage seconded by H. Stavely that the reports of the Council, Treasurer and Auditors be adopted. Carried.

The Association then proceeded to ballot for the election of officers for the ensuing year. The election resulted as follows:

President—V. Roy, Montreal.
First Vice-President—J. Nelson, Montreal.
Second Vice-President—H. Stavely, Quebec.
Treasurer—J. Z. Resther, Montreal.
Secretary—A. C. Hutchison, Montreal.
Members of Council—J. J. Browne, J. Haynes, H. M. Perrault, A. T. Taylor, A. F. Dunlop, Montreal; D. Ouellet, Quebec.
Auditors—W. E. Doran, S. Lesage, Montreal.

It was moved by A. Gendron, seconded by J. Perrault, that the next annual meeting be held in Quebec, the day to be fixed by the council in accordance with the by-laws. Carried.

There being no further business the meeting adjourned to meet again in the afternoon for the reading of papers.

Mr. Taylor desired to thank those who had assisted the Hanging Committee by sending examples of their work. He hoped that their example would be followed by others, and that members would also be found willing to present to the Association architectural books, which would form the nucleus of an instructive library. A vote of thanks to the Hanging Committee was moved by Mr. Brown, seconded by Mr. Rhind, and adopted.

AFTERNOON SESSION.

Mr. Victor Roy, the newly-elected President, called the convention to order and announced that five papers were to be read, the first of which, by Eric Mann, was entitled "Classic Architecture in Relation to Detail, with a Few Notes on Construction in Building."

Mr. Mann explained that the paper he was about to read was originally prepared to be read before the students, and was only presented to the Association owing to his having been unable to prepare something more suitable.

The paper, which is one of especial interest to students of architecture, is printed elsewhere in this number.

Mr. Chas. Baillairgé followed with a paper on "Escape from Buildings in case of fire."

Mr. A. T. Taylor presented a paper on "The Relation and Application of the Sister Arts, Painting, Sculpture, to Architecture," Mr. Rhind a paper on "The Architect as a Business Man and Artist," and Mr. Hutchison a paper on "The Plenum System of Ventilation as Applied to the New Surgical Buildings of the Montreal General Hospital," the latter being illustrated by a large diagram.

The President expressed satisfaction with the character of the papers to which they had just listened, and suggested that great benefit would result if monthly meetings of the Association could be arranged.

Mr. Hutchison said that such meetings were not a success last year, but he hoped it would be possible to do better in future. Personally, he would be pleased to contribute for the general benefit of the members any points of interest arising out of his experience.

Mr. Brown expressed a desire to see a spirit of greater fellowship prevailing among the members, and an indication of the determination of the Association to fulfil the objects of its existence.

Mr. Taylor having called the attention of the President to the presence of Mr. Curry, President of the Ontario Association of Architects, an invitation was extended to that gentleman to address the meeting.

Mr. Curry, after expressing the pleasure with which he had listened to the lectures, said that one of the greatest drawbacks to the progress of the Ontario Association, and he supposed of this Association also, was the apathy on the part of the members. With a membership of nearly 150 in the Ontario Association, and of nearly 70 in Toronto alone, only about 35 were usually in attendance on the meetings. The reason was, that members placed their personal business first, instead of the interest of the Association. He commended the plan adopted by the Toronto Architectural Guild, the members of which once a month go direct from their offices and dine together at a restaurant, and there discuss in an informal way matters of interest to the profession. The guild was very exclusive, admitting to its membership only desirable men and such as would attend the meetings. Those who failed to attend were dropped from membership. The organization had done much to promote friendship in the profession. The formation of a Dominion Association had been mooted, but he advised that they should endeavor to make a thorough success of the Provincial Associations before attempting the larger undertaking. Unfortunately some members of the Ontario Association, instead of seeking to assist the Association to elevate the standard of the profession, were seemingly only anxious to know what personal benefit was likely to accrue to themselves in return for their fees. These members took a wrong view of the subject. Notwithstanding, from their standpoint even, there were benefits to be derived. The Association library might be pointed to as one such benefit, and one which could be made of increasing value. The test of native building stones recently conducted by the Association was also of decided value to architects. In conclusion, the speaker remarked that goodfellowship and a desire to promote the good of the profession would best promote the success of the Associations.

THE BANQUET.

In the evening a considerable proportion of the members of the Association with a number of invited guests, pertook of a banquet at the City Club.

The toasts of Her Majesty, the Queen, and the Lieutenant Governor of the Province of Quebec having been duly honored, letters of regret at not being able to be present, were read from the Hon. Messrs. DeBoucherville, Beaubien, Flynn, Pelletier, Hall, Taillon, Casgrain, and Nantel. Letters of regret had also been received from the members of the Council of the Ontario Association of Architects, the President of which, Mr. Curry, was, however, present. The Secretary was sorry he had had no reply from the Canadian Society of Civil Engineers.

The Chairman: "Gentlemen, I have much pleasare in proposing the toast of "The Corporation of Montreal," represented here to-night by our worthy Mayor. It would be superfluous for me to try to speak in favor of the Mayor, for the simple reason that you know him better than I do, I hope he will give a few words of encouragement to this new Association."

The toast was drunk with enthusiasm.

The Mayor: "Mr. President and Gentlemen, I can assure you that I feel proud to be called to respond to the toast of the City and members of the Corporation. First, let me say that I had the honor to be a member of the Provincial Parliament when I think your Association was inaugurated by a charter, which with the assistance of the members for the City of Quebec, we succeeded in having granted: It is a satisfaction to reflect that our action in this regard has borne good fruit. The charter given to your Corporation has in the city of Montreal at least, chartered a body of men whose architectural skill excites the admiration of visitors to our city. It is the practice of some to borrow architectural talent from the other side; but let me say I have erected some buildings, and I always employ a resident architect. (Cheers). I can say as much on behalf of the gentlemen from Quebec. Montreal owes its great position today, as far as buildings are concerned, to the men I see around me, who have erected those noble buildings that are the pride of our city. As far as the Mayor is concerned, he may be only a cipher and figurehead; but let me tell you that the corporation, with all their faults, are trying to make Montreal a place to be admired. Sometimes we may be reproached with

heavy taxation ; yet what money we have to spend is, I think, spent in an honest and fair way by the representatives of our city. My friend, Mr. Roy, I am very proud indeed to know that you have been elected to-day President of this grand corporation. You are a credit as a body, and I hope that your society will live and prosper, and that the buildings that you will erect will equal any other buildings in the world."

The Chairman : "Gentlemen, we have a toast to propose, and that toast is a worthy one, for it is the toast of our sister Association of Ontario. (Cheers). I am glad to tell you that we have the President here amongst us, and I hope that next opportunity some of us will be able to return the compliment. (Applause)."

The toast was duly honored.

Mr. Curry : "Mr. President and gentlemen, I have to thank you for the very kindly manner in which you have drunk the toast. I think you have done it much better than we toast the Quebec Association. However, you have one advantage over us, you have better speakers than we have. We are indifferent speakers as a body; I am not by any means the best, but I am not the worst either, so you can judge for yourselves and form an idea of our calibre. I must say I prefer the actual work to the speaking. (Laughter). However, this Association and the Ontario Association have the same work before them, and that is, I think, educational work (applause). We have to educate the profession, and I think those of the profession will admit that there is a heavy work to do in that line. Next we have to educate the public, which I think is a much easier task. Our present trouble consists very largely in the fact that the profession as a body is badly educated. The members are as a whole rather inferior to what they ought to be. This is true of course of every profession, but I think we should strive to raise ours to be the equal of any (applause), and carry it beyond, if it is possible to do so. The architect requires to know everything, especially in the opinion of his client. He is supposed to be a good business man ; to know all about construction ; to know everything that a sanitary engineer knows—but not as some sanitary engineers know it (laughter). He is also supposed to be versed in heating, ventilation and acoustics—to know how to make a room a certain size in which a speaker can be heard with advantage to himself and to the audience ; he must be a thorough draughtsman, and know the history of architecture, and Heaven knows what else (laughter). In the end he has to become a specialist is some one branch or more. At the same time, it is really necessary that an architect should have a knowledge of all the branches that are necessary to the proper erection of buildings. He cannot know much about heating and ventilation unless he knows something of the methods by which they are to be carried out. A man cannot teach others anything, unless he knows something about it himself. An architect should above all things, have a pretty thorough knowledge of art. The question may be asked 'what is art?' That will have to decide itself. We know how our opinions change, we can even see it in the fashions of the day. The hat you wear to-day possibly you would not care to wear five years from now. So it is, we are continually progressing, still we can lay down a rule that what is reasonably good in art to-day will always be good. We can look back through the past and see that what was held to be good in architecture at any time, is always good. If a thing has any merit it will be recognized. Now the question that we have to do with as an Association is, what steps are we to take to produce a better educated lot of men than we ourselves are ? It is not sufficient that we should educate men up to a certain standard ; we have got to make them perfect within reasonable bounds. We can strive for perfection, although we can seldom or never attain it. There is little encouragement given to a man at present to become proficient. There are several things to discourage him. A man will say to himself, 'I am going to become an architect of merit ;' he settles down to work, and devotes himself to study. The result is that he remains unknown, and does not get anything to do. He may be thoroughly competent ; but someone else gets the work. Of course opportunities may come that will allow him to force his way to the front, and after that he can climb the ladder to the highest rung. It is our duty to raise the standard of the profession to the highest possible point. And how is that to be done? Well, we have already made considerable progress. Our Associations exist under special acts of the legislatures of our respective provinces. We in Ontario were able to secure a charter that did not give us all we wanted certainly ; but which nevertheless improved our position considerably. It is a question how we are to be able to carry out our duties, with the difficulties before us. We, however, hope to carry them out, though we have to make a struggle. We have that word 'registered' inserted in the act, and all our members refuse to use the word. They say that if they are architects, they are architects, and that it is not necessary for them to register or do anything else. If they have studied for their profession, they should be entitled to call themselves architects, and those who have not given the necessary time to the study should call themselves something else, not architects. We do not want to insist that those who wish to build must come to an architect to have the work done ; but we do ask that those who have studied and who have become members of the Association, through passing proper examinations or by whatever means may by be decided upon, should have the sole right to call themselves architects, and that the public, when employing a man should have some guarantee that he is a capable man and that he is what he represents himself to be. Then, if a man employs an incompetent builder, he will only have himself to thank for it. Now, I think that the Ontario Association of Architects has the desire, first and foremost, to educate. They have not so far taken any steps to make a tariff of rates, or to help themselves individually. We have thought it wiser to pursue an even course, to do what we can for the education of our members. We have now a library sufficient for ordinary purposes, so that the young student is thus saved considerable expense. The thing can be carried on indefinitely ; but we cannot do a great deal with a small amount of money. The fees are already high enough, and some members even complain as it is. They want the Council to show them some value. That we cannot do. But this we can do, we never propose to *give* them value ; but we propose to show them that they have *got* value. They paid their fees to become members with the object of educating the young members, and in so doing, advancing the profession and making such men an honor to the profession. If they are not prepared to pay fees for that object, then the sooner they retire the better. You, I suppose, are in the same position here. You have members who seek individual to gain by being members of the Association. Such men are not desirable. Only those members are desirable who wish to see the Association progress and see the members become an honor to the profession. It may be very nice to you to profit directly by a brother architect's bungling work; but, after all, these things are a drawback to the profession, and the public point to them as samples of architects capabilities, so the profession suffers. What we want to see is that when anything is entrusted to any member of the profession, good value is given, and that there can be no reason to grumble at the way in which the work has been carried out. I think I have occupied your time sufficiently, and will conclude by thanking you again for the very hearty manner in which you have honored the toast.

The chairman then called upon Mr. Baillargé, of Quebec, for a song, and that gentleman complied, singing a French ballad in most acceptable style.

Mr. Browne : "Mr. Chairman and gentlemen, as soon as you have composed you minds sufficiently after that beautiful song, I have the honor of proposing the toast of "The Canadian Society of Civil Engineers." The honor of proposing that toast is one which I esteem most highly. Canadian engineers beat the world. We are proud of them, and proud to see a member here to-night, and will only be too delighted to hear from him."

The toast was enthusiastically honored.

Professor Bovey : "Mr. Chairman and gentlemen, I am the victim of a deception. I was told that when I came here I should have a good dinner, and I should hear some good speeches, and that was all I should have to do. But now it seems I have to take the place of a far better man, Mr. Kennedy, our President, and I am unable to do that, and can only thank the members for the honor they have done us. I should like to take advantage of a tale which Mr. Curry was good enough to tell me during the dinner. A guest, when called upon to speak, got up and said he supposed he had had an invitation to be present in order that he might enjoy himself (laughter) ; but perhaps I might be allowed to speak not for the Canadian Society of Engineers, as they can speak for themselves, but generally. I agree with Mr. Browne that the Canadian engineers have a great reputation in all parts of the world. I would say that we at McGill College are looking forward with great pleasure to the visit of the Association to our buildings to-morrow, and I think you will agree with me when I say that for architectural effect, we have buildings that are unsurpassed, even if equalled, in any part of the world. I should not have dared to say this some time ago, but I have visited all institutions of this kind in Europe and the States, and I do not hesitate to say that there is not one of them better than, if there is any equal to ours in McGill. Time will not permit me to speak of all the benefactors who have helped to this end. We have not to thank one man only. We have first to thank Mr. William Workman, who was the first to help in this particular line. We have also to thank benefactors from all parts of the world. We have received assistance from places as far away as San Francisco, and even Mexico, as well as from Germany and other parts of Europe. I would especially refer to the almost unexampled munificence of one benefactor. I think we must be proud to have a man of such unbounded generosity among us as Mr. William Macdonald, and his generosity is not more remarkable than the wonderful manner in which he has carried out the work he has set himself to do. He only insists on one thing, and that is that everything must be carried out in the best possible manner. If there is anything wrong with the buildings, the architect alone is to blame. I have often heard it said, that although we have had large donations given us, we are never satisfied, and we are not; we want a great deal of money now. I should be sorry to hear any university say that they had enough. It would mark a crisis in the history of that university, and the point where that university is on the down grade. The more money a university can get, the more good a university can do. I will speak of one department, the department of architecture. Now there ought to be a department specially devoted to architecture in the great universities of the Province of Quebec, Laval, and also our own

great institution ; and I think that you, gentlemen, should all do your utmost to bring about this most desirable state of affairs. Many of you have rich clients and, if you have not persuaded them to spend too much already (laughter), you might persuade them to assist in founding, not merely a chair of architecture, but a department of architecture (cheers). It is of the highest importance I think in these days that students for this profession especially, should have the very best preliminary training. Young fellows preparing for the architect's profession, should have the very best training that school and college can afford. The best educated man in these days is bound to come to the front. That is the way in the United States. We have men in Montreal perfectly well able to superintend this education. The noble buildings we see on all sides, put up by our own men, are in themselves evidence that our architects are equal to anything that may be required of them. It seems to me strange that when any particular building for some special purpose is required, there seems to be a desire to go to the other side of the border, as if the work could not be done here. Sometimes—I am not quite sure—but I think that the buildings erected by foreign architects have tumbled in (laughter). I think our own men are best able to deal with our own buildings in our own climate (applause). I believe that the architectural details can be better worked out by our own men than by men who know nothing of the conditions with which they have to deal. I shall not detain you longer, but will again thank you for the honor which you have done me, an honor which I owe to my connection with McGill University. I must also thank you on the part of the Council and members of the Canadian Society of Engineers for the hearty good wishes you have expressed towards that great corporation. I believe your Association will raise the status of the profession ; that is the way in our Society. We have a Dominion charter, and we are an open corporation ; but an open corporation will in the long run have a greater effect than a close corporation. The moral effect of an open corporation is excellent, and in England has proved sufficiently strong to retain for its members all great works of architecture. A close corporation has of course certain advantages also. If a Dominion Association could be formed, you could exclude and keep out all undesirable characters, and retain only such men as would be known, not only in this Dominion, but also over the whole continent."

The Chairman : "Gentlemen, I will now propose a toast to the Press."

The first reply was made by Mr. Coté, who urged united effort on the part of all for the welfare of Canada.

Mr. Richard White : "Mr. President and gentlemen, I find it hard enough to say what I would like to say in English, and I cannot gratify your chairman by speaking in French. I am very pleased to be here this evening, and I am very pleased to find that you are inaugurating yourselves as a body. Judging from the experience of other professions, it is necessary that you should have an association of this kind. We find merchants, professional men, bankers and other classes having associations for their own mutual advantage, and there is no reason why your body should not also organize. I hope you will have every success in the objects for which your society was started, the general advancement of your profession, and the erection of beautiful buildings that will be an honor to Canada. I wish you every success."

Mr. C. H. Mortimer, of the CANADIAN ARCHITECT AND BUILDER, also responded.

Mr. Gendron was called upon for a song, but having a slight cold, delivered a speech instead. He said : "We have applied for a charter, and we have got it ; but it was first mutilated. We want a tariff, and a tariff which shall provide a just recompense for an architect's services, the same as in the legal and other professions. We have now in the house a tariff which we consider fair, and which we expect to see passed. I must say something for the Mayor of Montreal. He is the friend of the architects. He rendered justice to us at Quebec."

The Mayor : "Gentlemen, I am going to propose a toast that I know every one here will drink with the warmest enthusiasm imaginable. I am sure that every gentleman who is here will join with me in drinking the health of a gentleman who has so ably presided at your board, a gentleman who has been elected to fill the high and honorable position of President of your Association. I have known Mr. Roy for many a day. We have not been on the same side of politics, but we have always been friends. Mr. Roy is, like myself, a Montreal boy ; he has worked himself up to the honorable position which he now holds. In choosing for your President men like Mr. Roy, who has worked honestly to do credit to himself and credit to his name as a Canadian, you do honor to yourselves." (Cheers.)

The toast was honored enthusiastically.

The President : "Gentlemen, the noble words which the Mayor has just spoken touch me most deeply. I do not say they are true, for I have learned the complimentary facts he has stated to-night for the first time. If I am this night President of the Association of Architects of the Province of Quebec, it is not by reason of having solicited the honour. I was greatly surprised myself when, after having threatened the Association to resign several times, I found that I had been elected President. But, in this world we are not made for ourselves alone. I said to myself, 'I am the victim of something or somebody,' and when I found it was happiness to work for others, I fell into my role. Gentlemen, I thank you for the honor you have done me, and know that all I can do to make the Association a success, and all that we can do, will be cheerfully done. I have great confidence that we will attain our objects. There are ambitious men in our Association, but the greatest number are those who love the good of others. When the Association is recognized by the Legislature, the proprietors and capitalists will recognize them. The advantage of our Association is, that if all the details are well understood, the public will only employ architects recognized by the Association. It is their duty ; it is their interest. When our profession shall be held in proper respect by the public, you will see noble and good monuments erected. That is what works for the good of the public. We are all certain to live. The architect lives in every country; but when he is known, he lives better, for he has less work to do and more time to study his lines. I thank you cordially, and I shall do all in my power to cause the Association to increase and prosper in every way. I think that in this year we will try and show some lines of progress, and we will try to act so that all the architects will join with us to second us in our efforts."

Mr. Browne : "Mr. Chairman, I have the honor to propose the health of a man respected by all, who has held high positions amongst us, who has done a great deal for the society ; that is, our retiring President, Mr. Berlinquet." (Cheers.)

The toast was cordially honored.

Mr. Berlinquet : "Mr. President and gentlemen—In replying to the very flattering compliment which you have just paid me, I feel a certain sense of personal responsibility. The subject of Canadian architecture has already been treated at great length, and the progress of our Association has been the subject of much remark. I have great satisfaction, to which feeling is added a sentiment of vanity (fierté), or, better still, of pride (orgueuil). Our association has already given evidences of virility and stability (applause). But yesterday we were scattered over the whole surface of the Province of Quebec, and we did not know each other. To-day we are united into a corporation, united by a community of interest, for the purpose of advancing the profession, and obtaining for it the recognition which it merits among the ranks of the liberal professions. The work we have undertaken is a work of civilization and patriotism. Particularly will we labor to diffuse knowledge that will cause the progress of the exact sciences. I hope that the diploma of the Association will one day be highly prized. There remains for me one more duty to fulfil, namely, to thank you personally for calling me to the Presidency of your Association. I hope you will continue to second the efforts of your promoters, and work in a fraternal spirit. Our efforts to become a corporation are meeting with their recompense. It is that spirit of devotion which has made the stability and fortunes of all institutions" (applause.)

Mr. Dunlop : "Mr. President, I beg to propose a toast to "The Quebec members of this Association." I think that they are deserving of a great deal of thanks for coming here, and the only trouble is, we do not ask them to come here often enough. I know, for my part, that when we go to Quebec we are treated right royally, and we are glad to have an occasional opportunity of returning the compliment."

The toast was drunk heartily.

Mr. Baillairgé : "Mr. President and gentlemen, I thank you for the way in which you have honored the toast. I am sorry we are unable to be here in greater numbers, but the members here will express their appreciation of the way they have been treated. I am not accustomed to addressing audiences of this kind, but will call upon Mr. Peachy, who has been a city councillor, and is therefore an experienced orator."

Mr. Peachy : "Mr. Chairman and gentlemen—My honorable friend has paid me a compliment which I do not deserve. In the city of Quebec I worked for the city and I did my best ; but I never shone as an orator, and after the elegant speeches I have heard this evening, I am very diffident about addressing you. I am charmed at having come here, not only with the number of the members, but with the friendly spirits of which the society is composed. In the city of Montreal we observe that architecture has made immense strides ; we see the architects of Montreal occupying the highest positions ; the buildings of Montreal are equal to any in the United States. We, in Quebec, have not the same resources that Montreal has ; but, all the same, we shall follow in the right track, and do all we can for the instruction and education of our young architects."

The last toast, "The Retiring Officers," was responded to by Mr. Doran in the following terms :

"Mr. Chairman and gentlemen—I may take it for granted that in toasting the retiring officers, you desire thereby to express your approval of the greater number of their actions, and in the efforts they put forth for the advancement of an Association that was only in its infancy. It has, however, now attained a certain amount of growth, and the problem is, how to increase that growth and how to nurse the plant so as to make it a plant worthy of the soil. It is true that we have not accomplished everything we desired, particularly with reference to the act of incorporation sought for from the Legislature. We received something, but not all we asked for. The Quebec Legislature followed the bad example of the Ontario Legislature by mutilating the act by giving powers to 'registered architects,'

rather than to 'architects,' simply. However, for my part, I am of opinion that, having accepted the Acts, such as they were, the profession made a great mistake in not assuming the name required. I think that until the members of both Associations look seriously into the question, and assume the title given them, they will not, nor cannot have all the benefits, because, as it was pointed out by the President, up to and until the formation of this society, anyone could arrogate to himself the title of architect, and any one can still, and how are the public to distinguish? I think for my part that architects are foolish in not availing themselves of the protection, meagre as it is, afforded them by the act. In conclusion, gentlemen, allow me to thank you for the cordial way in which you have drunk the toast."

Some more songs and speeches brought a pleasant and profitable evening to a close.

SECOND DAY.

The members assembled at the Association rooms at 10 o'clock on Friday morning, and entering carriages in waiting, were driven to points of interest in the city. En route to the Royal Victoria Hospital, the attention of the visitors was directed to some of the old landmarks, such as the building which served as the residence of the first Governor of Lower Canada, now doing humble duty as a coach-house; the old Legislative buildings, now a hotel; the site of the old city wall, which still bears the appropriate name of "Fortification Lane"; Ontario street, formerly traversed by a creek, on the frozen surface of which when in youth some of the leading architects of the present day were accustomed to practice on the "ringing steel." "It is such features of reminiscence as these which go to make a city interesting," exclaimed one of the visitors, a remark in which everybody could coincide.

At the Royal Victoria Hospital the party were taken in charge by Mr. Rhind, under whose supervision the large buildings have been erected, and by whom the points of most interest in their construction were shown and explained. Those of our readers who examined the illustration of these buildings which we published a year or more ago, will remember that the site is irregular and uneven, yet this fact, which would ordinarily be regarded as a disadvantage, has by the skill of the designer actually been turned to advantage, whereby the bottom storey of one wing is on a level with the top storey of the other. The buildings have been erected of Montreal stone, and present an enduring appearance. The planning, being the work of Messrs. Saxon Snell & Son, the noted hospital architects, of London, was the subject of much interest. The buildings, which will cost about half a million dollars, are nearing completion, and will it is expected be ready for occupation early next year.

From the Royal Victoria Hospital the party were taken to the new Technological Building in connection with McGill University, of which Mr. A. T. Taylor is the architect. It is a most substantial structure, and its perfect adaptability to its purpose, evidences the painstaking thought bestowed upon it by the designer. The various parts of the building are isolated from one another by fire-proof doors. Professors Bovey and Workman received the visitors in the most cordial manner, and personally conducted them through the building, explaining as fully as time would allow the work which was being done, and the apparatus employed. After a peep into the draughting rooms, pattern rooms, machine shop and blacksmith shop, each fitted with the appliances necessary for imparting instruction of a practical character to the students, they were asked to behold what Prof. Bovey declared to be one of the best equipped testing laboratories in the world.

This laboratory contains two testing machines, representing the most perfect English and American patterns, each with a capacity of 100,000 pounds. These machines are operated by means of a small electric motor. They are capable of determining both the tensile and crushing strength of materials. A bar of iron, one inch in diameter, was subjected to a tensile test in the presence of the visitors, and after stretching three quarters of an inch, finally broke under a strain of 40,000 pounds. The laboratory also contains a chemical balance capable of weighing 125 pounds or the fraction of a grain, a *fac simile* to a small scale of the Montreal water works, by which the head of water necessary to supply a given population may be determined; apparatus for measuring the volume and rate of flow of water in a running stream, etc.

Here, as stated by Prof. Bovey, may also be seen the only standard cement testing department in Canada. The visitors were shown an automatically working testing machine. Cement briquettes are placed in a copper vessel containing water and subjected to a temperature of 100 degrees. If, after 24 hours, the briquettes blow, they are given a second trial. If, after the second trial, the briquettes blow they should be discarded. As in cement testing trouble often results from variation of personal manipulation, arrangements are being made in this department by which such manipulation will be done automatically.

Other features of interest were the electrical department, which contains a 250 h. p. dynamo driven by a sixty h. p. engine. There is not a belt in the place, the dynamo being driven straight on end. There are two engines each 500 h. p., and the space occupied by each engine is only 589 feet. The bottoms of the engine beds are hollowed out, which has the effect of preventing rocking.

One of the most interesting and valuable features of the institution is the library, which contains 6,000 volumes of scientific books, being one of the most complete libraries of its kind in the world.

At the top of the building, enclosed in glass, is a museum of mechanical models, which for completeness is said to be unequalled anywhere in the world. These models are the work of a celebrated German maker named Releaux, and were many of them made expressly for this institution. They illustrate almost every conceivable mechanical movement, and will be of great service, not only to the students of the school, but also to manufacturers and inventors. They are valued commercially at $8,000. Between the School of Technology and the new Physics building, which was next visited, there is a vacant space on which Prof. Bovey expressed the hope that another building would shortly be erected. When asked if his expectation was that this new building would be devoted to architectural education, he replied in the affirmative. He pointed out that even at present accommodation exists in the Technological building for this purpose, and the hope was expressed that the architects might be able to induce some of their wealthy clients to make the endowment necessary for the equipment of a Department of Architecture.

The Physics building, which is as yet incomplete, seems likely to be as perfect in its arrangement and appointments as could be desired. There is also in course of erection a new library building with a capacity of 150,000 books. The college library at present numbers 30,000 volumes. The stack-room is to be made thoroughly fireproof. In addition to the ordinary reading-rooms, there will be special study rooms in the basement.

Taking farewell of the college grounds and buildings, the party paid a visit to the new High School building, of which Mr. Hutchison is the architect. The front of the building is of pressed brick, and presents a very satisfactory appearance, while the planning of the interior appears to have been accomplished in an equally successful manner. The departments for the male and female pupils are at opposite ends of the building, with wide corridors between. Access is had to the lecture rooms from both departments. There are spacious play rooms in the basement, a library, a large gymnasium, and an assembly hall with a seating capacity of 1,200. The lighting facilities throughout the building are excellent.

From the High School the party returned to the Association rooms on St. James street.

It was moved by J. J. Browne, seconded by F. X. Berlinquet, that the Association tender its thanks to Principal Sir William Dawson for giving permission to the members to visit the new Science Buildings of McGill University, and also to the Dean and Professors of the Faculty of Science for their kindness in showing the members of the Association through the buildings.

It was moved by J. F. Peachy, seconded by J. Venne, that the thanks of the Association be tendered Mr. J. R. Rhind for his kindness in showing the members through the Victoria Hospital.

It was moved by J. Nelson, seconded by C. Baillairgé, that the thanks of the Association be tendered Rev. Elson I. Rexford, Rector of the Montreal High School, for his kindness in permitting the members to visit the new school and showing them through it.

The members then took leave of each other, and an occasion of much interest was brought to a close.

THE LATE W. H. HODSON.

Mr. W. H. Hodson, one of Montreal's old time architects, has passed over to the majority, an acute attack of pneumonia having ended his useful career. He commenced the study of architecture with one of the best firms in Manchester, England. Completing his studies there, he emigrated to this country some

THE LATE W. H. HODSON.

time in the fifties, practicing with great success in New York and Brooklyn. Coming to Canada in 1857 or 1860, he located in Montreal, and probably first distinguished himself on the building occupying the north east corner of Bleury and Craig streets, amongst others carrying out the works successfully of Messrs. Owen McGarry's and D. Ford's residences, St. Ann's church and St. Ennis, Alexandria. Mr. Hodson was a man of sterling qualities, his honesty being almost proverbial, his energy integrity lasting to the end.

THE TORONTO TECHNICAL SCHOOL.

Following is an abstract of the address delivered by Mr. John A. Duff, Principal of the Toronto Technical School at the opening of the second term on Oct. 3rd.:—

It has been announced that I am to speak to-night on "The Benefit of Technical Knowledge in Mechanical and Industrial Pursuits." It would probably be inferred that I would endeavor to enumerate the advantages and advocate the claims of Technical Education in general, but I do not think that any one will be disappointed at hearing that such is not my intention, for I feel sure that everyone will be more interested in hearing what facilties for such education are provided by the Toronto Technical School, and by explaining the scope and bearing of the subjects taught I think I can more effectively than in any other way make clear to you the advantages to be derived therefrom.

The history of the Toronto Technical School is brief. In December of last year the City Council passed a by-law, appointing a Board of Management and giving them an appropriation of $6,000 and the free use of St. Lawrence Hall. The Board at once began the work of organization; teachers were appointed, and the courses of study decided upon, and St. Lawrence Hall having been found unsuitable, this building was secured and the necessary alterations made with such expedition, that by the first of February the work of the session was well commenced. The attendance from the first was large, and was well maintained throughout the term, and very satisfactory progress was made.

Such has been the past. There is every reason to hope that the coming year will be still more successful and that the Toronto Technical School will rapidly become a great power for the dissemination of scientific knowledge and habits of correct thought. With additional teaching power we have been able to make the course of study more comprehensive. Trigonometry will be taught twice a week instead of once, which was all the time we were able to devote to it last year, and, if necessary, the classes in Arithmetic and Measuration will be subdivided. Arrangements have been made for three classes per week in Chemistry and Physics, which will enable us to provide a tolerably complete course on electricity—that mysterious power which seems destined to usher in a new era of civilization. There is thus provided for the current year the following distinct courses of study: Mathematics, including Arithmetic, Mensuration, Algebra, Euclid, Trigonometry; Practical Geometry, Descriptive Geometry, Mechanical and Architectural Drawing; Mechanics, including Statics, Kinematics and Dynamics; Chemistry and Physics, including Hydrostatics, Heat, Sound, Light and Electricity.

Each student is allowed to select his own studies subject only to the requirements of the time table. With only ten teaching hours in the week it is impossible to make provision for all the classes without having two different subjects occur at the same time, and thus to some exent the freedom of choice in the selection of studies is curtailed. The time table has, however, been carefully arranged, so that the least possible inconvenience will be felt from this source. For example, if a student has so far forgotten his Arithmetic that it would be necessary for him to take lessons in that subject, he would not be able, until he has become familiar with Arithmetical operations, to derive much benefit from the lessons in Mechanics. We have therefore put Arithmetic and Mechanics down for the same hour, and the students who find it necessary to review their Arithmetic, and who wish to study Mechanics, will find it not a hardship but very much to their advantage, to take Arithmetic during the present session and defer the Mechanics for another year. As the success of the student and therefore of the school depends largely on the proper selection of the course of study, let me briefly describe the different subjects taught, and incidentally mention some of the advantages derived from each.

Let us begin with Mathematics, the interpreter and herald of scientific knowledge, and without which little real progress can be made. Mathematics is one of the most potent instruments of scientific investigation, besides being the only foundation upon which exact scientific knowledge can be built. In Science and Engineering, theories are of little value unless they are exact and definite, and we cannot have this exactness without Mathematics. A knowledge of Mathematics is not necessary in order to understand the general laws of nature, but it is necessary in order to state those laws with exactness or make any practical application of them. Anyone can understand that water will flow through pipes, but no one can calculate the quantity which will flow through a given pipe in a given time without a knowledge of Mathematics. I do not mean to say that Mathematics must be pursued to its highest developments, but it is necessary to have at least a good working knowledge of Arithmetic, Algebra and Geometry.

The course on Arithmetic—the corner stone of Mathematics—will comprise instruction in numeration and notation, the operations of addition, subtraction, multiplication and division, the use of fractions and decimals, ratio and proportion, the method of extracting square root and the theory of logarithms—in short a complete course in Pure Arithmetic, including all the arithmetical operations which are used in the other branches of Mathematics and Science, but excluding Commercial Arithmetic, which is the application of the forgoing rules to the computation of interest, discount, stocks, annuities, &c., and which finds its proper place in the curriculum of a Business College.

Along with Arithmetic are taught the rules of Mensuration, by means of which the areas of surfaces and the volumes of solids may be calculated and compared. A knowledge of these rules may be required by any man at any time or place.

In Algebra the work will be the same as that which is ordinarily taught in the High Schools of Ontario, which is all that is usually required in pure or applied science. I will not occupy your time with a more particular ennumeration, but I wish to impress upon all intending students the vital importance of Algebra in chemistry and physics. In these sciences formulae occur which can only be properly expressed by algebraic symbols, and the only practical method of solving problems or determining an unknown quantity, is by means of algebraic equations. But if Algebra is of so great importance in Chemistry and Physics, it is absolutely indispensable to the proper study of Natural Philosophy or Mechanics. Very few calculations involving force or motion can be made without its aid, and without Algebra a knowledge of Mechanics must always prove to be incomplete and unproductive. What has been said of Algebra is true to almost as great a degree of Trigonometry and Euclid's elements of Geometry, Euclid has the further advantage of being one of the most perfect systems of logic that has ever been constructed, and no one can master Euclid without becoming a logician.

Let me here remark that the aim of higher education ought not to be so much to fill the student with dry facts, as to teach him how to use what knowledge he already possesses in other words to teach him how to think properly and to act accordingly. And one of the greatest works that a Technical School can do is to teach mechanics the *art of thinking*. To do this there is no study so efficacious as Mathematics, for there is no other branch of knowledge so exact and definite, and there is no other in which the reason alone is employed.

In Chemistry, it is proposed to teach the mode of occurrence, the nature, and methods of preparation of the different elements and compounds which are of importance in everyday life, special attention being given to those substances and processes which are of technical value, such as electrolysis, coal, and the manufacture of coal gas, iron and steel, mortars and cements.

Lying in the border land between Chemistry and Physics, is the study of the constitution and properties of matter:—a few lectures will be devoted to this very interesting subject.

Under Hydrostatics will be taught the general character and properties of liquids, and the theory of the common hydrostatic and hydraulic instruments, such as the hydrostatic balance, hydraulic press, spirit level, hydrometers, electrometers, etc. Along with hydrostatics, though scarcely belonging to it, come the physical properties of gases and the atmosphere, the theory of the barometers, pumps, balloons and siphons.

The course on Heat will embrace the nature, sources, transmission and general effects of heat, the theory and construction of thermometers, the determination of the melting and boiling points, freezing mixtures, distillation and evaporation, and the theory of steam engines.

Lectures will be given on the elementary theory of Sound and Light in, which the theory and construction of optical and musical instruments will be described.

Electricity will be taught in two divisions. The relation of Chemistry to electricity, and the theory and construction of electric batteries, will be described in connection with the course on Chemistry. In connection with Physics, there will be a course on magnetism and current electricity, the theory and construction of the dynamo, telephone and telegraph, and the applications of electricity in daily life.

In Chemistry and Physics the lectures will be illustrated by experiment as far as our apparatus will permit. We hope that very soon, though perhaps not during the present year, there will be a laboratory in connection with the school, in which practical work in Chemistry and Phys es may be done by advanced students. The advantages to be derived therefrom must be apparent to all, and let us therefore hope that it will soon be an accomplished fact. There will be a course on Practical Geometry, which is intended to give facilty in the use of drawing instruments and the construction of geometrical figures. It will be found very useful as an introduction to the course on Descriptive Geometry or the theory of projection. That on Descriptive Geometry will comprise the representation of objects by means of a plan and elevation, and problems leading up to and solved thereby, such as the determination of the form of the intersection of two cylinders or cylinder and a cone, together with instruction in oblique and perspective projection. This course, which involves the theory of drafting, is of great utility not only to those who are trying to perfect themselves as mechanical or architectural draftsmen, but to sheet metal workers and any whose occupation requires them to have some knowledge of working drawings, as pattern makers, boiler makers, machinists, etc. In connection with the Descriptive Geometry, practical instruction will be given in the drafting room in instrumental drawing, lettering, etc., for which purpose copies and models of machine and building construction will be available. This instruction will be given to the students individually and for this purpose the drafting room will be open, and an instructor will be present during every teaching hour of the school. A student who takes this course of practical work in the drafting room should be able by the end of the year to read a drawing without any difficulty, and also to make a fairly good original drawing, and at the end of two years he should be a fairly good draftsman.

The course on Mechanics will embrace the theory of vectors, the representation, measurements and laws of forces and motions, the theory of equilibrium, theory of the lever, pulley, and other simple mechanical powers, the calculation of stresses, theory of the simple beam, the transmission of force and motion, friction, work, energy, power, the efficiency of machines and the elements of machine design. I hope that this brief outline of the courses of instruction will enable intending students to choose wisely the subjects which they most require. But should there be any who are still unable to make a choice, the teachers will be glad to give whatever further information may be required. Most students will find that they will be unable to pursue more than two or three courses of study during the year. I would advise those who thus find it necessary to defer some of their studies, to take their Mathematics first, for the reason which I have already given, that a knowledge of Mathematics is essential to a proper study of the other subjects. From what I have said or from a reference to the prospectus it might be inferred that we expected to complete all our courses of study in one year, but such is not the case. In Algebra, Euclid, Descriptive Geometry, and perhaps some of the other subjects, two years will be required to complete the course, and it is expected that the advanced classes in these subjects will be formed next October. And, without interfering with the perfect freedom of choice now enjoyed by students wishing to pursue a special line of study, it is hoped that we will then be able to announce the programme for a regular course embracing two or three years. The experience of the past winter has convinced me that in Toronto the demand for technical education is urgent, but the citizens may rest assured that on the part of the Board of Management or the teaching staff of the Technical School no effort will be wanting to supply that demand.

LEGAL DECISIONS.

In the case of Lane vs. The Dungannon Agricultural Driving Park Associations, recently decided by the Court of Queen's Bench, Toronto, the contractor for the erection of a building for the defendants during its progress gave to various persons orders upon the defendants for sums due them by him, in the following form: "Dungannon, Sept. 12, 1890. To the directors of the Dungaonon Driving Park Associations. Please pay to D. M. the sum of $ —, and oblige (signed) T. F. H., contractor." The court held that these orders were not in themselves good equitable assignments of portions of the fund in the hands of the defendants. The evidence, however, showed that there was only one fund out of which the directors could be expected to pay the orders; that the nature of that fund and its origin were well known to all the parties, that when the contractor promised the persons with whom he dealt orders upon the directors, he meant to give, and these persons expected to get orders which were to be paid out of the contract price, and that the directors understood the orders as intended to deal with portions of the contract price, and to be payable only out of that particular fund. It was held that the court should look to the real intention of all the parties to the transaction, and give effect to it by declaring that the contractor did make an equitable assignment to each of the order holders of a portion of the fund.

TORONTO BUILDERS' EXCHANGE.

Some time ago we published particulars of the organization and growth of the Toronto Builders' Exchange; and on several occasions since have noted the steady development of the organization.

So great has been the progress of this body, that some time ago it became apparent that more commodious rooms would be required for its accommodation. Two or three weeks ago the Exchange took possession of new premises at No. 8 Victoria st. These premises comprise a large Board Room, suitable offices for the Secretary, Committee rooms, etc. In short, they afford every needed facility for the efficient transaction of the business of the Exchange.

On Thursday evening last the new Exchange rooms were formally opened by a banquet and social entertainment, at which upwards of 150 members of the Exchange and invited guests were present. Tables loaded with tempting viands stood waiting their arrival. After due attention had been paid to these, the balance of the evening was devoted to speeches, recitations music and social chat. The President of the Exchange, Mr. W. J. Hill, in a happy manner presided; the vice chairs were occupied by Mr. George Moir and Mr. George Oakley. The musical accompaniments were played by Mr. W. H. Hewlett.

The list of those present is as follows:

Invited guests—Messrs. H. B. Gordon, Grant Helliwell, Robt Ogilvie, Edmund Burke, S. G. Curry, Frank Wickson, J. Reggin, J. W. Siddall, James Smith, Prof. Wright, (School of Practical Science), J. Maguire, M. Guy, R. G. Kirby, Henry Simpson, R. J. Edwards, H. J. Webster, Chas. Walton, C. E. Bavington, S. H. Townsend, Henry Langley, Price, W. R. Gregg, Harry M. Blight, Harry Rich, W. H. Hewlett, John Knox, J. A. Pearson, Thomas Westlake, Thos. Young and D. Phillips representing the CANADIAN ARCHITECT AND BUILDER.

Members—Messrs. John Aldridge, Edward B. Axworthy, Benj. Brick, Jeremiah Bedford, John Bedford, Fred Bedford, Henry Bedford, Fred. Bayliss, James McCurdy, J. J. Blain, J. Bulley, John Brodigan, William Best, James Crang, Jethro Crang, John Vick, James Claxton, Richard Chalkley, John E. Curtis, William H. Rowe, John Carlyle, James Pears, Richard Elliott, L. B. McKenny, Capt. Neelon, M. A. Piggott, A. T. Fox, Jesse Ashbridge, Edward Gearing, John E. Goddard, John M. Gander, J. Lister Nicholls, Alfred Gardner, G. W. Gore, W. J. Hill, George Gall, Robert Harrison, W. F. Lewis, T. Hoidge, William Duncan, R. Hewitt, John Hanrahan, William Isaac, James Isaac, Daniel Livingstone, George Wright, Frank B. Lockwood, Henry Martin, William Maguire, C. F. Mitchell, John McMurren, George Moir, F. G. Nicholson, Archibald Orr, Robert Orr, George Orr, George Oakley, Fred Holmes, Scott (Ontario Lime Association), Isaac Price, John Price, William Park, James Priestley, Henry Phillips, Thomas Robinson, Robert Robertson, Thomas W. Self, Robert Snarr, William Simpson, Robert Simpson, Joseph Price, Thos. Sawdon, W. R. Simmons, Andrew Thomson, James B. Thomson, David Williams, James A. Wickett, John Wickett, William N. Watson, J. Watson, Geo. W. Walker, John B. Barnard, C. C. Witchall, Robert Whillans, William Whillans, William Woods, Ewart Farquhar, Samuel Young, and John L. Phillips, the Secretary.

The following gentlemen had charge of the entertainment:

Messrs. W. J. Hill, Geo. Moir, George Oakley, David Williams, John Aldridge, Benjamin Brick, William Park, James Crang, M. Murphy, J. L. Nichols, William Pears, Henry Martin, W. J. Burroughes, John M. Gander, Edward Gearing, Frank Powell, and to their well directed efforts is principally due the success of the occasion.

The toast of "The Queen," was proposed by the President, and responded to by singing "God Save the Queen."

The company were then favored with a song from Harry M. Blight, entitled "Polly," and on being encored Mr. Blight sang "Heart in Hand."

The toast of "The Toronto Architectural Guild" was then proposed by the President, accompanied with the names of Mr. Curry, Mr. Langley, Mr. Gordon and Mr. Smith.

In responding to the toast, Mr. Curry spoke as follows: "On behalf of the Architectural Guild I thank you most heartily for this toast, and for the manner in which you have just voted us 'jolly good fellows.' I think those who are acquainted with us architects will agree with me when I say we are 'all jolly good fellows.' I am afraid though, at times some of the members of this association are inclined to think we are not. Of course, there may be a little friction sometimes between us; but I think that on the whole we understand each other pretty well. Some architects in giving out contracts do so on the basis of getting too much value for the money spent; it is a question often of getting too little money for the work done. I think the builders are somewhat to blame for this state of affairs themselves, as a great many of the builders tender for work for much less than its proper value. If it was possible for the builders to make some arrangement among themselves, whereby they could get a proper amount of money for a proper amount of work done, it would be more satisfactory all round than trying to cut each other's throats. Now, there are architects and there are builders who are desirous of getting work, no matter at what cost—all they want is the work, to be able to say they have the work—who will tell you how they have been able to erect a certain building at an amount considerably less than some other of the builders can do. There is a competition among the architects to do business on the cheap plan; and the result is most unsatisfactory alike to the architects and the builders. As it is growing late in the evening and so much to follow, I will close by thanking you for your kind attention, and for the hearty way you have come together this evening and laid aside all grievances.

Mr. Langley said: I am very glad to have an invitation to meet so many of you this evening—so many faces I have been used to seeing for the past twenty-eight years. I will not endeavor to make a speech, as I am not a speech-maker. I heartily endorse everything Mr. Curry has said, especially as to the rates at which contracts have been taken.

Mr. Smith said: I thank the Builders' Association for the great pleasure of my being here this evening. I feel like a stranger in the city of Toronto when I see so many builders here. There were very few when I came to the city—very few of the fine buildings we now have in the city of Toronto were to be seen then. To the builders of Toronto we owe more, I think, than to any other class of men for the proud position our city occupies to-day. Any stranger coming into the city of Toronto, and especially American and English visitors say, Toronto takes second place to none. I came to Toronto in 1857, and I don't think many of you were in existence then (a voice—we were all built since then). I recollect the first year I was in business I only made $3.00. I only got $3.00, remember $3.00, for putting up a house, and then had to pay the taxes—don't talk about hard times any more. Here we have in this city nearly 200,000 inhabitants. I have travelled over a great part of the continent, and I can say our great buildings are equal in design to any of the great buildings on the continent. I suppose a good many of you are acquainted with me and a good many of you are not. I should like to shake hands with you all before I leave.

Mr. Gordon replied in the following words: As I look around and see the large number of intelligent faces here this evening, who are making their mark and leaving their mark in the way, as Mr. Smith has already put it, of the great buildings which are springing up on every side. I remember that you are the men who are making these lasting memories in our great city. We may look forward to good times when we have men of your calibre amongst us. The exchange of ideas, the exchange of thought and the stimulus of your meetings will have a beneficial effect upon business in this city in years to come. The very idea of a Builders' Exchange suggests a broad and comprehensive platform. While sitting here listening to the eloquence of the gentleman who preceded me, I was struck with the hospitality you tender to your guests on the opening of your new rooms; you have made an exchange of hospitality this evening, and if your hospitality is of the kind we are partaking of this evening, certainly you are adepts in the hospitality line, and I don't think you require any advancement in this line. You have certainly shown us all how to extend courtesy. Now as I look around and see the intelligent faces of men who have grown grey in their various trades, and see how they have prospered, I think it must be a good idea this building Exchange, where all can meet together and exchange ideas; I trust though that in this exchange of your ideas you are careful to be very lenient with one another. I hope in your exchange of ideas you will exercise moderation and throw about your ideas the cloak of charity. As to the method of tendering and this vexed question as to the price the tenders are put in at, and the difficulty there is of getting return for work done, I think that some satisfactory arrangement could be arrived at between yourselves which would do away with these vexatious questions. It has been done in times gone by, and if it was possible for the intelligent men of that day surely it is possible for you in a very short time to raise your tenders together, and then we will not have this everlasting cut in the prices to which we have been subject in the past. It would be a great relief to us all if means could be devised whereby a fair price could be got for work which is tendered on. The only way to accomplish this, is to have some properly constituted board to regulate prices, which would have the endorsation of the architects,—men who would have the endorsation of the Architects' Association, representatives from the various trades; men whose standing and position should be such that they would not be subject to reproach, men on whom the architects could rely, and furnishing, as it would, a comprehensive platform. We would then get better prices for our work, as hinted by Mr. Langley. I hope that the committee which have the exchange under their control, will speedily take means to accomplish this end.

Prof. Wright, of the School of Practical Science, spoke briefly in effect as follows: I am greatly pleased at seeing you all this evening. All I wish to say is, I hope that these new rooms and the formation of the Exchange will be beneficial both to the Builders' and the Architects' Associations and to the architects of this city at large. I am surprised this evening to see such a large gathering of builders here. I had expected to see about two dozen, instead there are over one hundred present.

Harry Rich then sang, "Boys of the Old, Old School," which pleased the boys of the old old school so well that Mr. Rich was forced to respond to an encore, in replying to which he favored them with "Polly."

The toast of "The Builders' Exchange" was then proposed by Mr. Curry, who made the following remarks:—"This Exchange will be able to show what the builders can do in the way of benefitting themselves, and also the architects, as our interests are practically one. It is a difficult thing to say just what could be done to promote the best of feeling between the architects and the builders, but something should be done to place things in a better position than they now are. It cannot be considered satisfactory when builders are competing to obtain work at rates which will simply give them day's wages at the best; that is the condition of things at the present time. At the same time it is a very difficult thing to say what would be satisfactory to all parties. Certain of the builders propose certain remedies; nothing could be accomplished without the builders being unanimous on this question. You must learn to have confidence one in another. If you can cultivate confidence, it will place you on the road to secure the needed remedies. I think the architects will do all in their power to assist you. Of course the architects do not care to interfere in matters not considered their own. Sometimes the trade unions undertake to dictate to the architects what they should do. I am not at all opposed to trade unions myself in any sense. I don't believe there are any of us who are desirous of having our work done for less than will maintain a man in comfort. It would be very unjust to get work done at a price which would insure but a bare existence. We can surely make more than a mere existence. Now, I hope this Exchange will result in the builders coming together and talking the matter over, and having greater confidence in each other, and arrange matters so that in future this unreasonable competition will not go on, although it seems to be the principle of the present day that everything must be cut down, to the detriment of the great majority, while the few reap the benefit. There are many points to be considered as between the architects and builders. In this matter of tendering, say a builder puts in a tender, and his tender is the lowest; an architect has to consider all tenders thoroughly, and he will accept the tender that is most judicious in the interest of the proprietor and the contractors. Then the builder who has put in the lowest tender thinks he is being played upon, and gets indignant. Now, it comes in as between the architects and builders very often that the contractors are trying to get the work done with as little work as possible, and the architect with as much as possible. I have been told that it was my duty to get all I could out of the contractors. The contractor, I think, should tender to do the work at such a figure as will allow him to perform the work to the thorough satisfaction of the architect. I think one of the great faults of the present day is that specifications are more or less useless. They are drawn up by the architect in rigmarole style. There has got to be a specification of some sort or other. An architect is not infallible; he cannot know everything. It is this question of inferior specifications which causes a great deal of dissatisfaction. If the architect knew just what class of work a proprietor wanted or about what he wanted to expend, there would be less friction in these matters. Now, I think it would be in the interests of the members of this Exchange to try if some means could not be adopted whereby a reasonable profit could be got for work done. If you find an architect is unreasonable in the manner of work to be done, you need not take work from his office. I think it would be well to drop out of that architect's office; that is the only way to put things straight. If the architect is unreasonable and unjust, why do not go near him. At the present time it is a very difficult thing to try and raise prices; everyone wants work; they must have work often, and they attempt to get it at a very low figure. Something should be done to improve the present condition. I think combines useless.

Mr. W. J. Hill, the President of the Exchange replied as follows: "On behalf of the Exchange I have to thank you for the hearty manner in which you have drank the toast of the Builders' Exchange. Away back in the early sixties, the first builders' association was organized in the city of Toronto. From that time until February last the organization assumed various shapes. After considerable talk last winter, certain members prominent in connection with the builders' section decided to write to the United States for information necessary to the establishment of a Building Exchange and as to what basis they were run on in the United States. Soon after application was made to the Ontario Government for an Act of Incorporation. The Builders' Exchange was formed for the purpose of providing valuable business information to its members. Immediately after we obtained our charter in February last, we enrolled 37 members, and from February up to the present we have issued certificates to 137 members. We have formed Sections known as the "Stone Cutters Section" "Builders' Laborers Section" and the "Carpenters' Section." The Plumbers' Section" will likely be formed inside of the next week or so. The felt and slate roofers intend to form a section soon. A short time ago we decided that our rooms were too small; we hadn't the accommodation for meetings that we required, so we set about making arrangements for new quarters. We have agreements with the Masons' Section and the Stone Cutters' Section. I want to say to our members to-night, stick to your agreements. There has been a little friction in one quarter but this has blown over. We have a Board of Arbitration in connection with our Exchange to settle disputes. There are a few questions as between architects and the builders that might be put on a better footing. I am satisfied that the outcome of this meeting will be the issuing of a few more certificates. I invite Mr. Smith and every member of the architects' association to our rooms at any time. You will find some of us there always. We intend to make this our place of business. Members of the Exchange gather here in the mornings, and transact general business here." I have again to thank you heartily for the manner in which you have responded to the toast of the Builders' Exchange."

The Vice-President, Mr. Geo. Moir, in replying to the toast, said: "I think the President knew very well that the time was short, and he also knew that I hadn't very much to say; and what little there was required to be said he took care to say himself. He has covered the whole ground most carefully. I can only endorse every word he has said in regard to the cordial relations which ought to exist between the architects and builders generally. I think we are all in the same boat. It is all very well to say that architects are with the proprietors all the time—I don't think this is the case.

Mr. Henry Simpson then favored the company with an exhibition of ventriloquism which occasioned great amusement. Many were the jokes got off at the expense of some of the members.

Mr. Harry Rich sang "Two Sweathearts" in capital style, and again had to reply to an encore. His encore number was "You Grow More like your Dad Every Day," which made a great hit.

The next feature of the programme was a short entertainment by Mr. George Oakley, illustrative of an Irishman's boyhood days on the farm. His impersonations of the cattle in the farm yard were very realistic.

The toast of "The Ladies," proposed by the President, brought forth a happy response on behalf of the fair sex from Mr. Elliott.

The company dispersed shortly after midnight with the feeling that they had spent an evening of solid enjoyment and profit.

WOODWORK IN ART.

I see it stated that Kerr Natter, the distinguished Austrian sculptor who recently died in Vienna, was in his youth a wood-carver, and by the practice of his humble craft rose to eminence in the highest of the plastic arts. Now, not a few of the best known artists of this country have served a similar apprenticeship. Sir Francis Chantrey, who died with a hundred thousand pounds, rose from the carving of ship's figure heads, through second-class portrait painting, to quarry in the gold mine of his very respectable, if not transcendent talents. The first serious efforts in art of Prof Herkomer and of Mr. Seymour Lucas were made with the gouge and chisel on a block of wood. James Burnet, too, practised as a woodcarver, and Opie professed the baser craft of a carpenter, and Romney of a cabinet maker. It is only another illustration of the truth that to the real artist the medium is nothing—nothing but a means to reach a higher end.

London Graphic.

A MANTEL SIX THOUSAND YEARS OLD.

It is seldom that wood, which was grown more than four thousand years before the Christian era, is used in the construction of a present day residence, and yet this really happened recently in Edinburgh, Scotland, where a mantel was fashioned from wood said to be six thousand years old. The wood, an oak tree, was found in a sand pit at Musselburgh, thirteen feet below the surface. Professor Geike, of the geology chair of the University of Edinburgh, after personally examining the strata in which the oak was found, said the tree, which was five feet nine inches in diameter, must be at least six thousand years ago, and describes it as a relic of neolithic man. It was in a fine state of preservation, due to the sand, and was easily workable.

FRAUDULENT CONVEYANCE—CONTRACTORS.

Where a firm of contractors who had undertaken to grade certain sections of a railroad, being unable for want of means to carry out their contract, conveyed to appellent all their property for equitable distribution among their creditors, appellant undertaking to complete the work and turn over the profits to the grantors' creditors after reimbursing herself for expenses incurred; the Kentucky Court of Appeals held (Cavanaugh vs. Riley) that the creditors of the grantors had no right to complain of the conveyance.

Mr. G. S. Dore has been appointed Sanitary Engineer of the city of Montreal, as successor of the late Mr. Radford.

The liquidator of the Danville, Que., slate quarry has sold the property to J. C. Stockwell and James Morrill, for $5,800.

The Laprairie Pressed Brick and Terra Cotta Company has been incorporated at Laprairie, Que., to manufacture bricks, tiles, etc.

Messrs. Taylor Bros., of Toronto, have purchased a device which will enable them to utilize the gas from the coal used as fuel under steam boilers for burning brick.

The Douglas Pine, one of the gigantic trees of Canada, is named after its finder, David Douglas, a botanic discoverer, at one time in the service of the Horticultural Society of London. He was an untiring explorer, and ultimately lost his life in a pitfall made for trapping wild cattle, being gored to death by one of these savage animals, which was in the pit.

CLASSIC ARCHITECTURE IN RELATION TO DETAIL, WITH A FEW NOTES ON CONSTRUCTION IN BUILDING.*

BY ERIC MANN.

The object of this paper is to draw the closer attention of students and assistants in architecture to the necessity of carefully looking into the work of detail in connection with the preparation of working drawings. How often do we see, an otherwise good piece of work spoiled in finish by badly executed detail in the moldings of cornices, string courses, dormer windows, porticos, exterrally and in panelling, plaster work, and inside finishings generally. In this connection I would strongly recommend the student or pupil to work from the examples of Sir W. Chambers' treatise on the "Decorative Part of Civil Architecture," and the works of Palladio contained therein, and to make drawings of the orders and detail the various members, from the pedestal, with its base, capial and dodo; the column, with its base, shaft, neck and capital; the frieze and entablature with the cornice as given.

The enlarging of the members of the various parts of the five orders, gives a pupil an excellent training in proportion, along with which he learns how to construct the various moldings. Nearly all these moldings enter into the composition of daily practice in stone, wood, plaster or iron work, and it is of the greatest importance that a correct style in forming these moldings, and a sound knowledge with regard to when they are correctly formed and proportioned, should be cultivated, as we see so much bad work done, evidencing a half educated author in the designs being carried out, no matter however small or great the work may be.

As the orders of architecture are the basis from which we chiefly derive the decorative part of our work, a few words on each order in passing will be in place here. As you all know there are five orders. Three, said to be of Grecian origin, are called Grecian, by the names of Doric, Ionic and Corinthian. The remaining two, being of Italian origin, are called Latin orders; they are distinguished by the names of Tuscan and Roman. Little is known at what period the orders were invented, and of their improvement we can only judge by the fragments of antique structures built in different ages, and still to be seen in various parts of Europe, Asia and Africa. The existing specimens of classic often quoted as examples of all that is fine, graceful and beautiful in architecture, may be taken as the Temple of Concord, portico of the Pantheon, and other parts of this structure in the Doric and Ionic; the arch of Constantine, Interior of Pantheon, Temple of Bacchus, and others, in the Corinthian, not forgetting the great Colloiseum in Rome, a specimen of Doric treatment. Besides these, in the sixth, or composite order we have the great Arch of Titus and others.

We find that a great author in classic architecture, named Perrault, has compiled a statement of comparative proportions of the various celebrated buildings in ancient Italy and Greece. His great intelligence and depth of research, has rather upset the pretensions of the great Vitruvius on the diminution of the shafts of columns.

A great deal might be here said on the subject of classic architecture, but the short comments I have made will be sufficient to illustrate the connection between the subject, and the object of my paper.

Following on this, I may add a few more words on the pupilage system in the old country. The pupil there is indentured or bound by a deed to be so many years, say five, in the office, and has to pay from three to five hundred dollars for this privilege. During this time he is put through a course of training, but at the same time is subservient to the rules of the office, and has to give all his time and work for the benefit of his employer. I have known pupils who turned out fairly good draughtsmen in two years, and are giving the benefit of their work to the architect whose office they are in.

This practice of working at classic architecture from books and examples is what is generally adopted in training a pupil for the first year, and if he is apt and likely to have a taste for the profession he has chosen, he will find that what I have said in the early part of this paper is not without its weight.

Although this reference to pupilage may appear like a digression from the object of my paper, yet it may serve to show the idea I have in connecting the early training with the successful and unsuccessful draughtsman.

Again, the careful working out of detailed work is one of the pleasantest parts of the office routine. The plans and elevations require to be well studied. The parts requiring drawing to enlarged scale must be correctly and carefully done, every molding and part exact as to size and figure; without this, full sized drawings cannot be correctly turned out. The pupil will find it comparatively easy to make a full sized detail, if he has got a perfectly correct enlarged scale drawing in front of him, and on this principle alone rests the secret of turning out correct detail for construction.

It is an evident matter to tell by the general design and detail of a building whether the architect employed has been carefully educated or not. I would like to draw your attention to the front or facade of St. Peter's Cathedral now being erected on Dominion Square. It is supposed to be an example of classical architecture, but if you study the detail after a course of Palladio; you will see how faulty it is. The pilasters, pediments, etc., of the front windows, bases and shafts, moldings, etc., are all out of the proportion laid down by the ancients, and which are accepted and worked upon at the present day. We have but few examples in Montreal of this class of works. The bank of Montreal is one specimen worth looking at, however.

Closely following on "detail," we find one of the most important elements embodied in the work of the architect's profession, namely, construction. By construction we mean the creation in solid materials bit by bit of the architect's conception and designs in a thoroughly practical, sound and workmanlike manner, and this is not, as it may look at first sight, such a simple task; on the contrary, it is the alpha and omega of the whole building, and demands close attention and watchful application on the part of the architect, because we consider that the architect is the creator of the structure as shown in his completed drawings, and we take it for granted that he has the genius and judgment necessary to carry to a successful issue the work of his brain and hands. The builder is the instrument set to carry this work on in accordance with the architect's intelligent plans and detail drawings, and under his instructions and directions. At this point, I would like to say, that builders as a general rule, are rather inclined to underrate the importance and nature of the architect's position, and to relegate to themselves a number of the duties devolving on the architect alone, and do not even stick at offering advice and guidance to the architect's clients or would be clients. This may be another digression, but I think that the profession ought to be upheld and its dignity fully maintained by us all.

The primary duty in construction, is a proper superintendence of the work during its progress. The foundations, on the sufficient construction of which so much rests, ought to be put in on a well levelled bed, free (if on a good earth bottom) from irregularities of surface, round stones, etc. The stones for footings should be large, and as much of a thickness as possible. The corners in all cases should have large heavy stones, and the joints broken so as to prevent an angle joint.

The building of rubble masonry represents a sort of puzzle, but the best built walls show a fair even surface on both faces, and also show in construction a sufficient number of through or bond stones in the wall. What exactly is a "sufficient" number, it is rather difficult to say, but an intelligent mason is always ready to do what is right on the architect's direction. Nothing is so miserable in building to look upon as a weakly built wall of small stuff packed full of rubbish and bad mortar from the trowel, and sad as it is to relate, this work can be seen going on here and there in the city to-day.

The proper external pointing of walls is a very vital matter, and one sometimes neglected, especially late in the season, when the mason is anxious to fill in round the walls; especially strong mortar ought to be used for this work, and the wall plentifully pointed and filled from the footing up as the work advances.

The matter of carpenter and joiner work is what may be termed the "skeleton" of the building, and in its fitness of framing and soundness of material, lies in a very large measure the quality of the house after one one year's occupation. How often do we see houses going sadly to pieces after one year's trial. The heating up begins to try the woodwork sadly. The studding, joisting, etc., begin to shrink and go, with the result that the plaster work shows gaps and cracks, notably in angles and staircases. A certain amount of this almost inevitable shrinkage is generally conceded and looked for, but if the timber is well dried and nailed, it is not nearly so marked, as in the case of wet stuff, which does not appear damp when being put up. In arranging the joisting of a building it is a good plan to have all the positions where plumbing work is situated trimmed "clear," with double trimmers, so as to prevent any cutting of joist for bends, etc.; also all openings to staircases, etc., ought to be double trimmed.

To prepare a building for the plasterer requires some thought and care. In the summer season it is not so particular, but in all cases we must see that the rough floors are well laid, and partitions all in place, the door casings all on, the grounds for plaster, carefully and well nailed on, care to be taken that they be left quite level and straight on face, as the neglect of this leads to unevenness in the skirtings, or "chopping," and consequently the loosening and breaking of the bond of the plaster. All roof openings should be attended to, and all necessary beads and casings put in place.

The hanging of the inside doors is another matter for attention. A good joiner will hang a door so that the door when shut appears about the same on both edges, but a badly hung door usually catches on either top or bottom hinge and presses in on the casing, all owing to not having been hung truly plumb; the casings of course must be quite square and true when put up. Locks may also be put on to look very slip-shod like, and not present that level, clean surface which the face plate ought to show on the door rail. The putting on of architraves is also important, especially when the skirtings and architraves are of especial design—the fitting at angles shows at once, and declares itself a poor or a good job.

In the matter of plumbing, gas and sanitary work, a very great deal has been said and written. You are all aware that our plumbers are not plumbers at all, but "sanitary engineers." I would, however, much prefer to deal with a good, sound, practical plumber, and there are many such in our own city. I consider that in all branches in the complex construction of a building, the architect's attention and vigilance are essentially necessary, and the plumber's "man" requires to be directed, however little he may like it, and now and then corrected, even. The improvements made in sanitary ware and the adoption of all iron soil and inside drain pipe, the ventilation of soil pipes, inside closets, etc., has made our houses very superior to what they were some fifteen years ago. I strongly advocate the system of open all ware, w. c. basins set on slate or marble slabs, copper lined cisterns with self-action, steel sinks, and where it can be afforded, white ware sinks, as for baths; procelain is very fine, but is exclusive as to cost. Copper lined is a good bath, also, and white ware open basins are to be recommended. For the soil pipes, should they have to pass under the cellar floor, extra heavy iron pipe should be used, enclosed in a trench covered on top with heavy wood covering, so as to be got at the entire length at any time; if possible, soil pipes are as well to be run on the wall, fully exposed to view, and every bend and connection accessible from bottom to top.

A great deal more might be said on this subject—in fact it is almost endless—but as long papers are not necessarily interesting ones, I will conclude by hoping that this one may have been found of some interest to most of you, and to join the President in his hope that my confreres will see their way to giving us papers as the season advances.

*Paper read at the Third Annual Convention of the Province of Quebec Association of Architects.

HAMILTON CORRESPONDENCE.

HAMILTON, Sept. 23rd, 1892.

EDITOR CANADIAN ARCHITECT AND BUILDER.

SIR,—In your issue of this month, your youthful correspondent at Hamilton has over-reached himself in his anxiety to belittle the sculptor who executed the carving on the Grand Opera House here, and who is now engaged on Mr. Geo. T. Tuckett's palatial residence. The mean attempt was made because that gentleman laughed at a stupidly crude and utterly impracticable drawing that the youth had made for the sculptor to carve from for Mr. Tuckett's building.

To show the absurdity of this (not to say wilful and malicious) mis-statement, I may state that no carving was done on Mr. Tuckett's residence until the 15th of September, several days after your valuable journal reached me. The sculptor, when I I drew his attention to the article, only smiled at the weak attempt of the lad to injure his reputation as an artist, as well he might, a reputation indelibly carved on most of the public and many of the private buildings that adorn, not only Hamilton, but many of the other cities of Canada.

Yours truly,

DORIC.

The life classes in connection with the Toronto Art Students' League have resumed their work, with every prospect of a successful season before them. The numerous sketches adorning the walls of the League rooms in the Imperial Bank Building bear testimony to the industry of the members during the summer months.

VOL. V.—No. XI. TORONTO AND MONTREAL, CANADA, NOVEMBER, 1892. { PRICE 20 CENTS $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),
PUBLISHED ON THE THIRD SATURDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.
C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
64 TEMPLE BUILDING, MONTREAL.

SUBSCRIPTIONS.
The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.
Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.
Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

WE had hoped to be able to print in this number the remainder of the papers read at the recent convention of the Province of Quebec Association of Architects, but the space at our disposal proves not to be sufficient for the purpose In consequence the interesting paper by Mr. Baillairgé, of Quebec, on "Means of Escape from Public Buildings in Case of Fire," is held over until next issue.

IN placing heavy weights on a floor, such, for instance, as a safe, it is often desired to know which is the best position for safety. This is easily determined. The floor boards will show the direction of the joists, and the safe should be placed in such a position that it rests on the ends of the joists, so that several of them support it. If the safe were placed against the middle of a wall to which the joists run parallel, the weight would all rest on two, or at the most three joists, and at the worst place, viz., the centre.

A BUREAU of Hygiene and Sanitation has been organized to prepare a collective exhibit for the Columbian Exhibition illustrative of the present condition of sanitary science. Dr. F. W. Brewer is the Superintendent of the Bureau. In this connection we observe that the Provincial Board of Health of Ontario has decided to assist in collecting the material for a Canadian special Sanitary exhibit at the World's Fair. With that object communication will be had with the local boards of health and with manufacturers and dealers in sanitary appliances.

THE preliminary arrangements have been made for a Canadian art exhibit at the Columbian Exhibition.—A Committee, representing the various art societies, will select the subjects at exhibitions to be held in Montreal and Toronto in February. A hanging committee will be appointed and a competent person to represent Canadian artists at Chicago. The hanging committee will assume the responsibily for the safe return of the exhibits to Canada. It is to be regretted that the enthusiasm which is being manifested by the artists has not also taken possession of the architects.

WE understand that some sixty designs were submitted in the preliminary competition for plans for public buildings at Victoria, B. C., to which reference was made in our last issue. Mr. S. G. Curry, President of the Ontario Association of Architects, and Mr. A. T. Taylor, member of the Council of the Province of Quebec Association of Architects, have been appointed to judge the designs, and to select the five which in their opinion possess the most merit. The authors of these will be required to submit designs in a final competition. Messrs. Curry and Taylor are at present in British Columbia making an examination of the preliminary designs.

Building contractors might well learn the lesson of how to estimate from the contractors for public works, who, while dealing with contracts of vastly greater magnitude, vary but slightly in their tenders. As an example, we may cite the case of the tenders for the construction of the Soulanges Canal. For section 11, five of the lowest tenders were in this order: $278,812, $281,749, $183,479, $289,649, $262,865. For section 12, six of the lowest tenders were as follows: $234,561, $235,218, $239,342, $240,990, $244,000. For section 13, several of the lowest tenders ranged as follows: $532,129, $552,629, $556,537, $559,695, These figures indicate that a more business-like method of esti-

mating prevails among contractors for public works than among building contractors, by which results much more accurate are secured by the former than are usually achieved by the latter.

A GREAT deal of well-merited praise has been bestowed upon the St. Clair tunnel as a type of modern engineering skill. The important feature of ventilation, however, appears not to have been successfully worked out. A suit for $75,000 damages is now pending against the Tunnel Co., the plaintiff being the widow of a brakeman named Hawthorne, who died from suffocation while the train on which he was working was passing through the tunnel. It appears that the train parted in the middle while in the tunnel. Hawthorne was on the rear part and was suffocated before assistance reached him. The company is said to be considering the question of using electric cars in the tunnel.

THE first prosecution under the new scaffold by-law of the city of Toronto, took place during last month. The prosecutor was the city Building Inspector, and the defendant, Mr. James Hill, a Cleveland contractor who is building a brick chimney stack one hundred and seventy-five feet high for the Toronto Street Railway Co. Mr. Hill contended that his men were perfectly satisfied with the scaffold, and further, that the most dangerous part of the work had been completed, but the magistrate refused to allow him to proceed until the scaffold was re-constructed from the bottom up in accordance with the requirements of the by-law. For the information of builders who may not be familiar therewith, we print elsewhere in this issue the provisions of the law.

A PROPOSAL has been introduced by Alderman Lamb in the Toronto Council for improving the present market accommodation. The suggestion is that an architectural competition be instituted for the purpose of procuring designs for the alteration of the present St. Lawrence market. It has likewise been suggested that it would be desirable to erect new buildings on the esplanade, convenient to the proposed Union railway depot and the steamboat landing. The latter proposal is one well worth considering. The lake front would be almost as convenient of access as the present location, and unless the present buildings can be so altered as to provide all necessary accommodation for the next fifteen or twenty years, it would be more satisfactory to erect new ones.

The recent outbreak of diptheria in one of the choicest residential districts of Toronto, has drawn attention to the foul condition of the sewers as being the most probable source from which the disease could emanate. It does not appear to be a rule of the city service that the sewers must be flushed at regular intervals; consequently it is left to the rain to cleanse them, and there having been but little rain for a month or two past, they have become the receptable for all manner of filth. This condition of affairs, bad enough in itself, is accentuated by the fact that the only means in use for the ventilation of sewers are the gratings in the manholes in the centre of the street and on a level with the pavement. From these manholes there is being constantly emitted into the atmosphere the poisonous gases engendered by the foul contents of the sewers. It is quite time that some proper method of ventilating the sewers was adopted. It would be a comparatively easy matter to placein inconspicuous positions a sufficient number of ventilating shafts for this purpose.

A railroad man in Broad Street Station, Philadelphia, recently said that the Pennsylvania Railroad Co. have for years been looking for something to take the place of glass for use in glazing the station roofs and for similar positions. He said that the heat and smoke given off by the engines, added to the vibration caused by moving trains, has the effect of breaking the glass, however well it is bedded. The cost of putting in new glass always is considerable because of its high position and the difficulty of getting at it, but that is nothing to the expense that would be sure to come should a piece of cracked glass fall and injure a passenger. Railroads have not only to buy the best because of economy, but have always staring them in the face possible suits for damages. What is required is some sort of a glass having imbedded in it a steel wire mesh so that should the glass crack the wire will hold the pieces up. A paragraph in a foreign paper states that a material of this kind has lately been put on the market in Germany. It is, however, only made in small sheets, and is therefore practically useless.

A correspondent of the Montreal *Gazette*, writing from St. Johns, Nfld., takes a sombre view of the future of that city. He points to the fact that the value of property destroyed in the recent conflagration amounts to upwards of $20,000,000, while the total sum paid in insurance reaches only $4,800,000, leaving the community poorer by $15,000,000. "One cannot but smile," says this writer, "at the shallow, optimistic views propounded by some here, who have little insight into the reality of matters. These talk flippantly of building up at once a fine city far superior to the former; and even hint airily that the fire is rather a good thing, and that we will soon be in a better position than ever. It is well to be hopeful, but to indulge in childish fancies and hug illusions can do no good. The expenditure in work, and the increased employment given will create a temporary boom and seeming prosperity; but our capital is diminished, our houses, public buildings, educational establishments, halls, etc., have to be restored, and all this implies hard work continued through years. We have to go back fifteen or twenty years, and like a colony of beavers whose dam has been swept away by a flood, begin the work afresh. The beavers are not jubilant or jaunty over the flood that has broken up their homes and destroyed their labors, but quietly go to work and grimly face the disagreeable facts of existence as part of the ordinary course of nature. Our shallow-pated optimists, who are generally non-workers and only talkers, void of all practical talent, had better 'consume their own smoke.' Their idle chatter only irritates the real workers."

It is stated on the best authority to be the intention of the Montreal Street Railway Company to extend its lines as fast as possible to the outlying districts, with the object of attracting population from the crowded central parts of the city, to build up the suburbs and increase the street car traffic. Such a policy would no doubt result profitably to the company and would be the means of greatly improving the appearance of the city as well as the conditions of residence therein. In this connection we quote with approval the following from an editorial article which recently appeared in the columns of the Montreal *Gazette*:—"The Quebec order of domestic architecture runs to terraces. A man's lot is twenty-five feet front running to a lane in rear which is too often the common receptable for all the refuse of the abutting proprietors' dwellings. His end wall, like his lane, is common to his neighbor. This fashion of crowding may be a survival from the days the towns had walls to keep out the Indians and intra-mural space was too valuable to waste in gardens. The fact that the area of the city was small also no doubt tended to strengthen the traditional style, which had a further excuse in the desire of the people to live as near their places of business as possible, owing to the poor means of transport available. The house-building ways of Montrealers have also been copied by their suburban neighbors, even when there was no excuse in the dearness of the land occupied. The result is that Montreal and its offshoots present one of the most densely populated areas, outside of New York city, on the continent. The city would be healthier as well as more attractive and home-like, if there was greater individuality in the citizens' residences—if families lived in houses, instead of being domiciled in sections of a block. It is unfortunate that the era of suburban development now promised from the modernizing of the street car service, does not also promise all that is desirable in the way of a change. Farms miles out in the country have been surveyed and sold on the 25-foot plan, and, because the people do not think for themselves, the vendors have met with a success that was hardly anticipated. The process of emancipation from the old rule may evidenely be slow unless some real estate man, more keen than his rivals, sets the example that once seen will be appreciated. There is such a thing as costly economy in house building, and Montrealers illustrate one phase of it when they sacrifice individuality, homelikeness, healthfulness and appearance for the sake of half the cost of a dividing wall."

ARCHITECTS' FEES.

CHARLOTTETOWN, P. E. I., Oct. 28, 1892.

Editor CANADIAN ARCHITECT AND BUILDER.

DEAR SIR, I would be glad if you could answer the following questions in the next number of the CANADIAN ARCHITECT AND BUILDER:—

What is a fair charge by percentage for preliminary drawings (plans and elevations) specifications and estimates of proposed alterations and repairs to a large public building built of free stone? The building was erected about 50 years ago and is in a very bad condition, parts of the work being almost dangerous. There was included in the preliminary work a careful report upon the present condition of the building, and the cost was figured at $18,000. The work, however, was never carried out.

Yours truly,

C. B. CHAPPELL.

[The charge for full professional services for a public building is 5% of the cost of the building when completed. In case of the abandonment of the work, the commission is calculated from the estimated cost of the building, and is for the degrees of partial service as follows:—

1. Preliminary studies, 1/5 of the full commission as above.

2. Preliminary studies and general drawings and specifications sufficient for estimate and contract, ½ of the full commission as above.

3 Preliminary studies, general drawings, specifications and details, 4/5 of the full commission, as above.

For the alteration of premises a charge in excess of the above is made for surveying, measuring and plotting an existing building, and for such other extra work as may arise in the preparation for or supervision of alterations. This charge is based upon the time occupied.—EDITOR C. A. & B.]

A REPLY TO "DORIC."

HAMILTON, Oct. 22nd, 1892.

Editor CANADIAN ARCHITECT and BUILDER.

SIR,—In reference to "Doric's" letter in your last issue, I must say there was no intention on my part to injure anyone's reputation; such an idea never entered my head. The two buildings referred to have been the principal jobs here this season, and I simply criticized the carving as a matter of course; as far as that goes, I strongly reiterate what was said in the notes, and feel quite satisfied that competent judges would do the same.

"Doric" says: "No carving was done on Mr. Tuckett's residence until the 15th of September, several days after your valuable journal reached me." The ARCHITECT and BUILDER was not published till Saturday, September 17th, and, as you know, the notes were in your possession at least one month before that date. At the time these were written I positively state a large amount of the carving on Mr. Tuckett's residence was not only started, but very nearly finished, if not quite; there has been nightly little done on some of it since then.

As far as the drawing referred to is concerned, I had not the slightest idea that the sculptor had laughed at or in any way criticized it till reading "Doric's" letter; it quite surprised me. I contend, however that there is nothing crude or impracticable in it, and am quite ready to have my copy of the drawing inspected. The idea is certainly somewhat new, and doubtless it was reluctance to leave the rut of old ideas that caused the sculptor's hilarious criticism.

In conclusion let me say, that although this sculptor may have done highly artistic work on many other buildings in Canada, it does not in the least alter the present case; in fact it is more to his discredit that this work should have been turned out.

I am, yours faithfully,

C. H. ACTON BOND.

THE O. A. A.

November 5, 1892.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR, What has become of the Ontario Association of Architects to which I have paid a subscription for two or three past years. We in the country look anxiously in the CANADIAN ARCHITECT AND BUILDER for some signs of its existence, but month after month goes by and we begin to think it is dead. Surely for an Association of such importance to the Province, we, the members, might expect to hear something between the annual meetings, but now we never even see any reports of board or Council meetings, which used occasionally to appear. We have been waiting now for nearly two years to see the results of Mr. Townsend's investigations and experiments on the building stones of the Province, which Mr. Curry recently stated was of decided value to architects, and naturally we should like to know whether any progress is being made towards the erasion of the word "Registered" from the Act. I see in a speech of Mr. Curry's at the meeting of the Province of Quebec Association that the work of the Ontario Association has apparently dwindled to the training of students, and that he expects we should all pay for this laudable object, and he infers that he does not want men to be in the Association who are not willing to do this without expecting to receive benefits. I think we all joined the Association under the notion that it was to be for some rather more general good to the profession than that, and personally I do not see the advantage of remaining a member for the sole purpose of educating young fellows in Toronto.

The Quebec Association has hit upon an excellent idea, that of monthly meetings of the members in town. Now, if the city members would meet monthly, read and discuss papers and have the papers and discussions published for the use of country members, we should certainly be benefitted. It seems to me that the policy of our Council is to keep quiet why, I do not know, unless it is that they fear to excite opposition, but I would remind them that opposition is generally very beneficial and in this case would certainly rouse us to do something for the Association in the way of helping against contrary influences, whereas now we are gradually losing all interest.

Now that the Association has shown us that some communication between the architects of the Province is a good thing, I for one would certainly like this communication to be kept up, and if the Association cannot do it except for two days or so in each year, there is certainly room for some other organization, at any rate for the use of country members.

Mr. Curry says that the Toronto Architectural Guild dine together once a month or so and discuss matters of professional interest. He says that the Guild is very exclusive, by which I conclude he means that it is composed of probably the members of the Council who happen to live in Toronto and other members of the profession who have large practices. Now, most of these, if not all, must be members of the O. A. A.; then why, if they can meet and talk together as a Guild, can they not do so as the Association and let us outsiders have the benefit of their discussions? I would gladly subscribe that they may dine together if they would only do this for me in return.

I do not wish to put myself forward as the mouth-piece of country members, but I feel sure they must all feel pretty much as I do, and it would be a good thing for us all if others would write to you their feelings in the matter.

I suppose there is to be a convention next February, and I have no doubt that the city members will do their best to make the country members welcome, and I do not forget how well they have entertained us, but pleasure apart from the meetings of the convention, will do us from the country very little real good. I understand now since Mr. Curry's visit to Montreal that we are very selfish to expect any good; we ought to come up in flocks or droves to benefit the students, but unhappily I cannot afford to do that, and I am afraid I must confess to being one who puts his "personal business" before the training of the youths.

Apologizing for the length of my letter, I am yours truly,

A COUNTRY MEMBER.

TORONTO ARCHITECTURAL CLUB ORGANIZED 1889

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—Will you kindly allow me space in your columns to draw the attention of the architects of Toronto to the work of the Toronto Architectural Club? It has been felt by the committee that some special effort must be made this year to augment the membership, and that a better understanding of its aims and objects might accomplish this end. This seems especially desirable as the club commences this session in new quarters, under a new name, and I may add with new and higher aspirations.

In a city the size of Toronto it requires the active co-operation of every member of the profession to make such an organization the success it deserves to be. To those who have not had the privilege of attending its meetings in the past, it might be said that the importance and interest of the papers read have been of such an order as to place the Club on an equal footing with other architectural associations not only of this country, but also with those of the United States and of England.

Owing to the fact that during last season classes were conducted for the benefit of students under its auspices, the impression may have been formed that it is merely a students' club. This of course is not the case.

A series of papers and lectures, interspersed with exhibitions, socials, etc., is being arranged for the winter's programme, which will be of undoubted merit. It is then asked that the efforts of the officers and the labours of those who prepare the papers may be backed by the regular attendance not only of the architects of the city, but also of their students, and of that large class which is, in a non-professional way, interested in the advancement of art and architecture in our country.

The meetings are held fortnightly, in "The Forum" on the south-east corner of Yonge and Gerrard streets. At the next meeting, which will be held on Monday evening, Nov. 21st, Mr. J. Wilson Gray will read a paper on "Glimpses of Chicago and the World's Fair Buildings." A hearty invitation is extended to all interested to be present that evening, and to have their names enrolled as members.

Yours truly,

A. H. GREGG,
President T. A. C.

THE INTERIOR OF A HOUSE.

The following paper on the above subject was read by Mr. C. H. Acton Bond, of Hamilton, at the meeting of the club on October 17th :—

It is a little difficult to know exactly where to begin in speaking of the interior of a house, as so much may be taken under this heading. The object of this paper, however, being to start a discussion, it will be as well to plunge right in and chance the consequences.

Whatever may be the size or cost of a house, its interior should suggest "A Home," and it is with this as an ultimate result always in view that I shall treat the subject. Of ordinary sized houses and those where a minimum of expenditure is allowed for the interior, very little will be said, as deductions can be made from the more elaborate schemes to suit these particular cases.

That portion of the interior of a house that comes under the supervision of the architect ordinarily includes the finish of doors, windows, walls, ceilings, floors, mantels, etc., and in considering these it will be necessary to speak of the various woods and their finishes, wall hangings and decorations, relief ornament, hardware, marble, tiles, grates, etc. Every apartment in the house should receive a distinctive and suggestive treatment according to its purpose, but there should yet be preserved a harmony throughout; that is, the contrast between adjoining rooms or halls should not be inharmonious, as this produces a very unpleasant effect and gives a feeling of unrest to the occupant. It will only be necessary to speak in detail of the principal rooms, as this will give a sufficient idea of the whole scheme. The general practice of treating the dining room rather heavier and in darker tones than the other rooms seems to be very appropriate; the serious business of eating is transacted here, and the occupants are usually sitting and in a comparative state of rest. In the drawing room it is quite the reverse, and a much lighter treatment is suitable. The parlor or sitting room should have a treatment somewhat between; the reception room being chiefly devoted to social formalities, should receive a light and simple but dignified finish; there should not be much elaboration in the halls, and the tone ought to be rather subdued with a view to harmonize with the various rooms. The bed rooms generally should be finished in a light and cheerful manner. Special rooms, such as a billiard room or smoking room, would have to be finished very much according to the taste of the owner.

If a room is badly proportioned, it can be greatly improved by a little thought on the design of the finish, as the length, width or height can be strongly emphasized by lines in that direction. In designing the woodwork it is well to bear in mind the final completion of the scheme, so that it may have a look of unity. The main lines should be carried round unbroken as much as possible, and wherever features are introduced, such as cabinets or sideboards in a dado of panelling, they should work in with the general heights; it is a very difficult matter to apply successfully any scheme of decoration to a room in which this has been neglected.

If it is decided to finish a house in natural hardwood, some care will have to be given to its selection for the different rooms. Antique, English or quartered oak, walnut, rosewood, black ash and similar woods would do for the dining room, the lighter woods, such as bird's eye, curled or white maple, satin wood, sycamore, or white mahogany, being suitable for the drawing and reception rooms; in the sitting room, cherry, sycamore, gum-wood, white walnut, etc., could be used, and oak, cherry, or gum-wood, would be appropriate for the halls; in the bed room it would be better to choose from the lighter woods.

Of course, the hardwood finish should all be built up, as this gives the best results; it allows the wood to be better seasoned, and prevents cracking and warping. The veneer should be about ¼ inch thick, built on a thoroughly dry pine core made of small pieces well glued up. When the hardwood is being put up, the house should be well heated, as this will avoid to a great extent the opening of joints, etc., after the work is completed.

For the finished floors white oak is very suitable, as it is a good hard wood and looks well; maple, pitch pine or white pine would make a good floor for the kitchen apartments. The flooring should be in narrow widths and could be laid rectangularly across the room, diagonally or in simple patterns, with butt or mitre joints. Pattern floors of different woods tongued and grooved together or simply glued on a backing, are sold by a number of manufacturers. This is known as parquet work and would look very well in some halls. Care should be taken not to have too much variety in the pattern of the woods.

For vestibule or conservatory floors, encaustic tiles, mosaic work or rubber tiles would be more suitable than wood.

In finishing wood consideration should be given to its natural effect, and this should be followed as much as possible; for instance, red mahogany looks best with a highly polished surface, but oak looks best when finished dull. For all ordinary finishes hardwood should be well filled. Wheeler's is one of the standard patent fillers, but there are many good ones on the market. Some painters prefer to mix their own, and usually make them of corn starch, plaster of Paris and linseed oil. Coarse grained wood, such as oak, ought to have two coats of filler. A very satisfactory way of treating oak is to give it two coats of linseed oil after being filled and each coat rubbed down with beeswax and turpentine to a dull finish. For woods such as cherry, maple, sycamore, etc., two coats of hard oil varnish applied after being filled and each coat rubbed down with pumice stone and oil, will give a good result; for a highly polished surface, from four to six coats will be required according to the nature of the wood. For finishing natural pine, apply one coat of white shellac instead of the ordinary filler, and then finish with two or three coats of finishing varnish rubbed down at each coat.

Boiled oil is commonly used for painting on account of its drying qualities, but raw oil is more reliable and gives a better result in the end; lead paint should be used in preference to zinc as the latter shrinks and creases. The hardwood floors should be filled and finished with Butcher's or some other reliable hard wax finish, or this may be done with beeswax and linseed oil.

There is such a variety of ways to treat a wall that it will be impossible now to speak of every method. The whole height may be finished in wood paneling, or the woodwork may just come high enough to form a dado; often it is nothing more than a base, and when this is so, the space above can be broken up in the decoration as dado filling and frieze, or just filling and frieze. Sometimes the frieze can be omitted with good effect, and the wall finished with small mouldings at ceiling or merged into ceiling without any break.

The most common wall decoration is wall paper, but of this not much will be said. It is produced with flat and relief patterns. Block, satin and mica or silk papers all give good effect. An excellent idea in wall papers has just been brought out in New York; it is known as the "Soudanese" pattern. In this the dominant color of the filling is carried into the dominant color of the ceiling; thus the frieze serves to interblend the wall and ceiling. Ingrain papers are now being used with patterns stencilled on after being hung. Good effects can be obtained if the colors are well chosen. Munro's ingrain papers are the best.

Besides wall papers there are many other hangings used for walls, such as tapestry, silk, embossed leather, Japanese leather, Lincrusta-Walton, anaglypta, stereo-relief, lignomur and a number of others. Japanese leather is a relief hanging decorated by bronzes and gold by the manufacturers in antique effects; it makes a very suitable filling for a dining room where there is a dado of oak. Lincrusta-Walton is a composition relief material, stamped; the relief work is very sharp and clean, but has rather a precise effect; it can be painted or decorated to taste. Anaglypta is another stamped relief material; it is not so sharp in its relief as Lincrusta, but has more of a modelled effect. Stereo-relief is a fire-proof composition hanging, cast in flexible moulds; it can be obtained in both high and low relief and with a perfect undercut; from the process of its manufacture the stiffness and preciseness of stamped hangings is avoided, and a free artistic effect is gained. Lignomur is composed of chemical wood fibre in bold relief; it can be painted, stained or varnished just as if it were natural wood.

The ways of decorating walls without hangings are just as numerous as the many varieties of hangings in existence and it will be impossible to speak of them all now, as this alone would require a whole evening. They may be painted in many ways and left either plain, with stencilled ornaments, or frescoed; if the plaster is stucco finished, an effective way is to gradate the color, and if consideration is given to the way the light comes into the room, beautiful results can be got. Immense color combinations can be got by studying the tints on autumn leaves; the harmony on them is perfect and the tints are so varied that the scope of their application is unlimited.

Linspar is a mineral composition for decorating walls and ceilings; it can be used as a stucco finish, combed or brought out in relief, and is well adapted to modelling ornament. Some painters get the same effect with a composition of their own; it is then usually known as plastico; papier mache and other relief ornaments can be worked in with it and the whole decorated as desired. An effective way to decorate relief hangings, such as lincrusta, anaglypta, etc., is to paint them, rub verdigris into the hollow, and then apply gold leaf by a roller or pad; this will just catch the high lights and accentuate the relief; the result is an antique effect and looks immense. Whistler, the American artist, obtained a striking effect in a small room by a very novel method; he painted the walls a pure black and then overlaid this with a semi-transparent yellow; the result was a misty foggy look, and the room appeared to be much larger.

Rooms treated in the Adams or Rococco styles may be finished in white or ivory enamel, picked out with gold or silver; for the very best work of this kind the wood should be of cherry, as it is so close grained and hard; the next best wood for the purpose is white wood or poplar. The wood should first be filled, then given two or three coats of white lead paint and finished with two coats of enamel, rubbed down at each coat. The white lead paint is put on to give a body to the work. Plaster should receive a coat of white shellac instead of being filled and then about four coats of white lead; after this the enamel is applied as on the woodwork. Patent enamel may be used, but, if preferred, it can be made with zinc white and light hard oil varnish. Zinc white is used in preference to lead in the last coats, as it is a purer white, but would not do for the foundation on account of its shrinking quality. Silk hangings can be panelled or draped all around the room either with a frieze of other materials or of silk festooned and caught up with relief ornament, having swags of cord and tassels. This of course does not include every way of treating walls—for instance, they could be kalsomined or whitewashed!!

Ceilings may be tinted, papered, panelled or finished in relief work. Heavy oak beams and cross beams make an excellent dining room ceiling; the panels could be filled with relief hangings, modelled plaster or stucco work, which would look well if tinted a rich brown and broad plays of lights introduced in it from the direction of the windows by chromos and vandykes. Ceilings of plaster ribs and modelling give great scope to the decorator, as also do ceilings having stereo-relief or carton-pierre ornament. Ceilings can also be painted in oils or water color. Alabastine is a patent water color preparation which can be obtained in delicate tints and gives good results.

The mantels should be of similar finish to that of the room, and grates and hearths chosen with a view to the general harmony. An open fireplace having an enamelled cream color tile backing, hearth of similar tiles with Mexican onyx border and facing of Mexican onyx, with simple oxidized brass edging frame would be very suitable in a room finished in ivory enamel. Enamel tiles are preferable to glazed where delicacy of tint is required, such as would be in this case Briquette tiles should be used for backings, as the flat tiles are liable to be cracked off by the heat. Care should always be taken to proportion the hearth, both in size and color, to the rest of the work. Bronzed relief linings look well with the darker woods. Enamelled and ordinary pressed bricks can be used for both fire places and mantels. With the Roman, Carthaginian and moulded bricks now made, great variety in design can be obtained. Other materials, such as stone, marble and slate, are used for mantels, and in England cast iron is largely used, painted to correspond with the room.

Hardware is a subject which should be taken up separately, but as this forms part of a complete whole, something must be said about it. This, as every other part, should be chosen with regard to the ultimate effect. Furniture can be obtained either plain or ornamented, and in a great number of finishes, such as plain brass, bronze, nickel plate, silver plate and gold plate. Most of these finishes have sub-finishes; for instance, oxodized effects and matching one finish with another. Iron is finished effectively by the Bower-Barff process which converts the surface of the metal into magnetic oxide of iron and makes it absolutely rustless; this is very appropriate for halls and rooms finished in oak.

In a large house it is well not to carry the same finish all through, but consider the effect of the different rooms. A drawing room finished in enamel and gold would look well with gold plated furniture, and so on. Of course, it would not be well to get too much variety this way, and a little care must be exercised. A look of completeness is given to the work if attention is paid to small details, such as finishing that portion of a butt hinge which shows inside a room to correspond with the hall; the heads of window head screws should also have the same finish as furniture of room.

In conclusion, it is only necessary to repeat that everything should be designed and selected with regard to the whole effect, and if this is done we ought to have as a result, a thoroughly artistic and satisfactory home.

PUBLICATIONS.

WE have been favored by the Secretary with the R. I. B. A. Kalendar for 1892-93, which we find to be quite as instructive as usual.

Mrs. Schuyler Van Rensselaer's papers on the great English Cathedrals, which have been appearing in *The Century Magazine* for some years, have at length been issued in book form, making a handsome, royal octavo volume of 400 pages. These articles which have been written by an amateur for amateurs, have been carefully revised by the author and greatly augmented, and with the splendid illustrations by Joseph Pennell —154 in number—present a vivid panorama of St. Pauls, Canterbury, York, Wells and the other great Cathedral churches of England. The book, considered either from an historical or a critical standpoint, is a valuable addition to ecclesiastical literature. Published by The Century Co., New York. Price $6.00.

"CANADIAN ARCHITECT AND BUILDER" COMPETITION FOR A CITY HOUSE.

THE CANADIAN ARCHITECT AND BUILDER invites competitive designs for a city dwelling, to cost $15,000, and to be erected on a lot 30x125 feet. The lot will face the narrow way, south, the long way, east. The main west wall of the building must stand on the party line between the lots, and the main east wall must come upon the street line. There is to be no enclosed area for lighting.

The building is to contain three clear stories above ground, to be constructed of stone, or of stone and brick, with sloping or flat roof. No overhanging tile or shingle work will be allowed.

The entrance may be on either front, at the option of the designer.

The number and location of rooms and the purposes which they are to serve is left to the judgment of the designer.

Competitors will be required to furnish plans of basement and three upper stories, and elevations of south and east front. Perspectives may be submitted at the option of the competitors. Floor levels must be marked on tee side of the elevations.

This competition is restricted to architectural students and draughtsmen in Canada.

Drawings must be made on sheets of heavy white paper or bristol board, 14 x 20 inches in size, and must be drawn sufficiently coarse to allow of their being reduced to one-half the above size. Drawings must be made in *firm, strong lines*, with *pen* and *black* ink. No color or brush work will be allowed. Each drawing must be marked with the *nom de plume* of its author, and the author's name, *nom de plume* and full address, enclosed in a sealed envelope, must accompany each drawing sent in.

Drawings must reach the office of the CANADIAN ARCHITECT AND BUILDER, Confederation Life Building, Toronto, on or before the 4th of January, 1893. The right is reserved of publishing any drawing sent in. Drawings will be returned to their authors within a reasonable time after the competition is decided.

The first premium will be $15.00, and the second, $10.

The merits of the designs will be decided by a committee composed of three members of the Ontario Association of Architects, and their decision will be final.

COMPETITION FOR PUBLIC BUILDINGS AT VICTORIA, B. C.

The decision in the preliminary competition has just been announced. Out of sixty designs submitted the five exhibiting most merit are declared to be those by the following architects:—J. Francis Brown, Toronto; Thomas C. Sorby, Victoria; F. M. Gardner, Chicago; W. J. Rattenbury, Vancouver; J. M. Connor, Boston, W. H. Skillings, Seattle, the last named two having joined on one design. We congratulate the Canadian architects upon the excellent showing they have made in this competition, and especially Mr. Brown, who has but recently commenced practice. It is to be hoped that a Canadian architect may succeed in winning first place in the final competition.

THE ERECTION OF SCAFFOLDS.

WE reprint below the by-law recently passed by the City Council of Toronto governing the erection of scaffolds:

All scaffoldings used by bricklayers or other builders in the erection, repairing, altering or improving of buildings, chimneys or other structures, shall be built and constructed as follows:—

BUILDERS' SCAFFOLD.

Standards or uprights to be of live, sound Norway pine, tamarac or spruce (tamarac preferred). Distance between each standard eight or ten feet, and butts of said standard placed in the ground to the depth of not less than two feet six inches, and when placed upon stone flagging or granolithic sidewalk, to be put in good sound cement or other barrel, or a box two feet square by two feet six inches high, and filled with sand or other suitable material. The standards to be not less than four and half inches at butt, and two and a half inches at the top diameter, and in a very high scaffold, to be increased in size.

Ledgers same material as standards, not less than three inches diameter at small end, and no ledger to be taken off the standards that would allow a greater distance from the ground than ten feet. Putlogs to be of ironwood, white oak, or other suitable material, the said putlogs to be butted, flattened or squared at the end which enters the wall, and not to be removed according as the scaffold rises. One course of planking, the entire length of scaffold, must remain on each tier of the said putlogs. The putlogs not to be less than three inches diameter clear of bark. Three putlogs to be placed under planks twelve feet in length, that is to say, one putlog at each end and one in the centre. (When planks sixteen feet long are used five putlogs shall be used.) Planks to be two inches in thickness, and of sound pine, spruce or hemlock, ten or twelve inches in width.

Scaffolds to be stayed from ledgers on to the joists through the openings, and in the absence of openings, to be stayed by other sufficient means.

Racking braces to consist of poles and tied with ropes. Ropes not to be less than sixteen feet in length, and five-eighths of an inch thick, except in case of small scaffolds, when rope one half inch thick may be used.

Ladders in all cases to reach five feet above the landing stage, so that plenty of hold will be afforded men when landing off.

When bricks are laid from the inside of fire-proof buildings, there shall be a temporary floor of two-inch plank laid on the girders or temporary joists all around the inside of walls and not less than six feet wide, and when bricks are laid from the inside of buildings not fire proof, which have joists not over fourteen inches apart, then the temporary floor may be of one-inch boards six feet wide and placed all around the building.

In all cases where the inside scaffolding is built from the foundation the same as the outside scaffolding, the temporary floors above mentioned shall not be required.

When trestles are used, the height to be from four to six feet and to be made substantial, of good material, and when a scaffold is formed by putting trestles one upon another it shall not be over eighteen feet in height, that is to say, not more than three trestles shall be used of the height of six feet each.

Where required all overhead protections to be placed fully under scaffolds. When building out to the street line, boards or planks to be placed where the workmen pass under.

All scaffolding used by carpenters, in the erection, repairing, altering or improving of buildings, chimneys or other structures, shall be built and constructed as follows:—

CARPENTERS' SCAFFOLDING.

All uprights of said scaffolding to be 4 x 4, sound and free from objectionable knots, the brackets nailed to them and to the building, and to be one inch in thickness and not less than ten inches wide, properly nailed to building and upright; and when there is no opening to nail said bracket, then a piece one inch thick and six inches wide to be notched to secure the bracket, and nailed solid to the wall and to the upright. The boards laid on this to walk on to be two-inch plank, sound and free from knots, or else two one-inch boards, laid one on top of the other.

When bracket scaffold is put up, the leg to be sound and not less than 2 x 6 on edge, set at the proper angle to prevent the bracket from tipping from the wall.

When scaffold projects from windows, the bracket to be one inch thick by not less than ten inches wide and six inches deep, both brace and bracket well nailed to window, and the brace well nailed to bracket also.

The City Commissioner shall forthwith after he has approved of the plans of buildings proposed to be erected, as required by Section 32 of By-law 2468, see that the scaffolding used in the construction of such building shall conform with the foregoing provisions of this By-law, and prosecute all persons who may proceed with the erection of buildings using scaffolding which is not constructed in accordance with this By-law, and in the event of the City Commissioner finding a scaffold, which in his estimation is unsafe, and after due notice to the contractor, the same is not made satisfactory, the said Commissioner may take such proceedings against him as he has power under this or any other By-law.

Any person convicted of a breach of any of the provisions of this By-law shall forfeit and pay, at the discretion of the convicting magistrate, a penalty not exceeding the sum of fifty dollars for each offence, exclusive of costs.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT and BUILDER).

The Building Inspector wishes to secure the amendment of the by-law governing the erection of fire escapes, so as to bring the owners of large boarding houses under its provisions.

It is understood to be the intention of the newly appointed Sanitary Engineer to endeavor to secure the adoption by the Council of a by-law to provide for the regulation of plumbers and plumbing.

The death of Mr. Geo. H. Mount, who for nine years filled the position of assistant to Mr. Lacroix, the City Building Inspector, took place at St. Hyacinthe last month.

The sum of $20,000 has been subscribed for the erection of a monument to the late Sir John A. Macdonald. The committee, representing the citizens, which has in hand the erection of the monument, will proceed at once to collect the subscriptions. A number of sculptors, foreign and Canadian, have been asked to submit designs.

Mr. Douglas Sladen gives the following description of the old cathedral of Notre Dame at Montreal, in a letter to the New York *Sun* reporting the doings of the Duc d'Orleans and the Compte de Paris on the occasion of their visit to the city. "In America Montreal is the City of Churches, and the finest of them all is Notre Dome, rebuilt in 1824 on the site of the church of 1672, with towers 227 feet high, and a good deal of the majestic appearance of St. Sulspice, of Paris. The Seigneurs of the island of Montreal are the Fathers of St. Sulspice. Inside, no church on this continent so recalls the carving and color and richness of mediæval Catholic churches, like the roof of Ely Cathedral, or the wood screens of Totnes and Dartmouth. There are many suggestions of Dartmouth in the interior. One must examine it in a subdued light, or not too closely, for its ornamentation bears the same relation to the solid richness of mediæval work as Japanese goods prepared for Western markets bear to the genuine old Japanese, made for some great Daimo, and sold and resold, until they arrive at the stall of the curio seller. The galleries have very handsome wooden areading, and there is a great deal of carving about the reredos and the pulpit and elsewhere, but the effect is the effect of things that would be poor without paint—not of painted oak. Though it will not bear critical examination from an eye accustomed to the work done when the monks were their own masons and carpenters, the whole effect is rich and singularly harmonious and spirited. This great church will seat from ten to fifteen thousand people.

A commission composed of Mr. H. Wallis, Mechanical Superintendent of the G. T. Railway, Mr. Howden, Government Inspector of Dredging, and a third party yet to be named, has been appointed to inspect and report on the work done in Montreal harbor during the past year.

HAMILTON.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

As might be expected there is not very much work going on just now, but for this season of the year the outlook is not bad.

Architect Clohecy is making alterations to the Loretto Convent, which will cost about $10,000.

Extensive alterations will be made to Christ Church Cathedral Sunday School by Architect Mills who has just completed the Zion Tabernacle Sunday School.

A residence to cost about $10,000 is to be erected by Architect Balfour on James street south for Mr. C. M. Counsell.

Messers Lawry & Son are making important alterations and additions to their pork factory on Wentworth street under the direction of Architect Balfour.

A large addition will be made to the Hamilton Pottery by Architect Mills.

Architect Balfour is making additions to Gomph's brewery and also to the Grant-Lottridge brewery.

Architect Stewart is putting up a residence on Hughson street.

A hotel is being erected on top of the Mountain, in the east end, where it is intended to construct another incline railway.

The intersection of John and King streets has been selected as the site of the proposed monument to the late Sir John A. Macdonald. The base is now in course of erection. The statue itself is expected to arrive shortly from England.

Carving in this city seems to receive very little attention from the architects, and the result is in the majority of cases that the building would look better if it were left off; on the recently completed Bank of Hamilton, however, the carving is very successful; it is well designed and well executed; on the City Hall the execution of the carving is good, generally speaking, but in some places the design is not at all up to the standard; one of the panels on the main tower is particularly bad. On the Public Library the carving is entirely devoid of artistic merit, and it seems a pity that on a building of this character such should be the case. On the Canada Life building the carving is very good, and not only improves the building, but is a credit both to the architect and sculptor.

A joke is going the rounds at the expense of the watchful guardians of the peace in Hamilton. A well known plumber and two of his assistants found it necessary to work all night in repairing some pipes in a store. They were discovered by the police, who mistaking them for burglars, quietly surrounded the house and had a patrol wagon in waiting to receive them. When their identity became known, the representatives of law and order retired with as much dignity as the circumstances would permit.

THE ARCHITECT AS A BUSINESS MAN AND ARTIST.*

By J. R. RHIND.

The architect must be, first, a business man, second, practical, and third, artistic. Is is of the last I have most to say.

The first is necessary to the drawing up of agreements, and conducting and negotiating for the carrying out of work, so that extras or omissions, should any occur, may be settled in a fair and just manner, and so that the employer may be protected from any loss by the failure of the builder to fulfil his contract. The want or lack of a business way of settling work, drawing up agreements and specifications, or badly drawn and insufficiently illustrated plans, are primary causes of misunderstanding and disagreement, lead to litigation, entailing serious loss of time and giving much worry and trouble—and worry will kill a man in half the time that hard work will—and making one ask the question: "Is life worth living?" I would certainly answer, "Not the life of an unbusinesslike architect." Business capacity will come by experience, though sometimes dearly and bitterly bought, and wise is the man who takes his mistakes in a right spirit and avoids the sunken rocks and treacherous under currents which he will surely meet, as every one of us here has no doubt done, who steers his business affairs by the light of his past experience, and guided by common sense, carefully avoids past mistakes and blunders.

There is, as you all of course well know, great differences in clients; with some clients from the first moment you put pencil to paper to the last stroke of the pen as you sign your name to the cheque in payment of your services, it has been a series of successes; everything you do is appreciated; this gives zest and pleasure to your work; you feel inspired as you design; you strike out good and original ideas; your suggestions are approved of and carried out. With a client of this kind you invariably get the pick of the contractors (a good contractor is more than half the battle) to carry out the work well and quickly, and when you are finally and promptly paid you sign your name to your cheque with an extra flourish and dash, and feel that though easily earned, you gave good value for your money.

But the other kind of client, who first bargains what you are to be paid and who thinks your charges exorbitant, you never seem to be able to please. After making innumerable drawings, your plan is at last decided on, you call for tenders which of course come to far too much money; the plans are reduced and invariably spoiled, the work is cut down to the cheapest kind, the cheapest and nastiest contractors are given the work. The work goes on; your amiable client thinks it is not good enough and blames you; he begins to alter and add here and there, wants better inside finishing, better locks, better everything, till the bill of extras amounts to almost as much as the whole contract price; your client refuses point blank to pay, and if the poor unfortunate architect has not got every order for extra work in writing, he gets up one fine morning and finds that he has to attend that abomination of abominations, a court of law, to be questioned and cross-questioned by an "imp" of a lawyer, and is ready to declare to himself as he wearily drags his limbs homeward, "Life is certainly not worth living."

These are the two extremes of the business part of the profession, and let us all pray that we may never meet the kind of client last described.

Next comes the practical part of the profession. The architect must know and use the most suitable material for the many different parts of his building, and proportion them to withstand the strains that will come upon them, in the strongest, most enduring and economical manner. This knowledge can to a certain extent be acquired by study alone and by being taught by another, but this is not sufficient, you must have practical experience, that is, the actual seeing of the work as it is carried out. When you make a mistake yourself or the builder makes a mistake, for the best of us are not infallible, then your inventive faculty in construction comes into play, and you are as it were "put on your mettle" and in rectifying your mistake you learn something which you did not know before and perhaps would never have learnt, unless you had blundered. Experience thus gained is one of the richest jewels in the architect's practice; it can only be obtained by experience, and wise is the man who humbly and thankfully stores this precious knowledge and who is able to bring it forth and apply his mayhap dearly bought, but rich experience, when occasion demands, and thereby successfully overcomes the difficulties in his way. But foolish is the man who does not profit by his experience. The pitfalls in his way are many, but he often discovers his calamities when they are brought about by his own pig-headed stupidity.

Now we come to the third, and to the architect the indispensable quality, viz., the Artistic—it is this quality which distinguishes the architect from the civil engineer, or mere builder. It is not bound by any rules that can be acquired and retained by memory ready to be fired off when occasion requires. One must have the artistic quality or he cannot design, it is like music, one must have an ear before he can distinguish one melody from another.

This artistic feeling is stronger and keener in some than in others; we cannot all be geniuses, but that should be no hindrance to our designing in good taste. We cannot all be Mozarts or Beethovens, but that is no reason why we should not enjoy the simplest melodies, or join in singing a chorus, or warble a song, though perhaps some of us in trying to warble might not add to what you would call "the concord of sweet sounds."

In short, one having an ear for music, it is possible to be trained to be a musician in the same way one having natural taste can be trained to design in good taste, by being told what is good and what is bad, and thus to be enabled himself to discriminate between good and bad, to have pointed out the difference between ornamental construction and constructed ornament; on this last hinges the whole question of good and bad architecture—one must construct first, and then ornament the construction. One sees this ornamental construction brought to the highest point of beauty in the architecture of the middle ages, but when construction became the main object and the architect tried to see with what little support he could erect his buildings, they began to have an attenuated appearance, and though strong enough as time has proved, these buildings can never satisfy the artistic feelings within us; they look like what my countrymen would call "no very canny," and you feel a certain relief when you get a good distance away from them. Some of the principal qualities of good design are: the building must be strong and look strong, and to look strong, it must have strength and more than enough to set the mind at rest and satisfy you that it is, as the Yankees would say, "there to stay."

I do not mean to say that the stronger you make your building look the more satisfactory the effect. One is just as liable to err on the side of heaviness and clumsiness as attenuation and meagreness, but there is a just proportion between height and breadth and depth which the trained eye alone can discriminate and which never errs on the side of weakness.

To make a thorough good design one must not draw a pretty picture only and go no further, but must draw every particle of detail full size; the detail of a building goes more to show the well trained architect than the whole design; the general design may be good, and the detail being what you would call unarchitectural, it condemns the whole building; on the other hand the design may be meagre and the detail good, and thereby it retrieves the whole building and brings it into the sphere of good design.

This study of detail is one of the most interesting and absorbing in the profession of an architect, and the correct rendering of detail goes more to show the educated architect than any other point in a building.

The best way to study detail and design is from the actual building, not only to stand and look at it, but to measure and draw it, transfer it to your sketch book and make it your own, and you will discover as you draw fresh beauties which you did not before observe. I do not mean the buildings on this continent, but those of Europe. One to get the purest water must go to the fountain's head; in the same way one must study the works of the the old masters.

If this Association is to attain to the highest degree of usefulness in the architectural profession in Canada and has at heart the raising of the profession to the highest and most respected position in the land, we must endeavor to do all in our power to this end. Let us begin with the training of our students who are the future architects of the Dominion, and determine that they shall have every opportunity and facility to gain a true and correct knowledge of architecture and the many branches of knowledge with which the architect of to day is familiar, especially the highest training of an artist in its broadest sense. Let us have a travelling studentship, to be won in competition, to enable the most capable of our students to enjoy the inestimable privilege of studying in Europe. I say privilege, because it does not matter how clever one may be, he is heavily handicapped in the race for excellence unless he studies in Europe the glorious works left to us by our fathers.

We are in a new country untrammelled by any school or manner of design; our requirements are different from any part of the States or Europe; we have more difficulties to contend with in the construction and design of our houses than any other country in the world; we have tropical heat and arctic cold, then let us make it our aim to make this architecture of Canada characteristic of Canada. The architecture of the past has all been guided more or less by conditions of climate. In Southern Europe we see the flat roof and open piazza and balcony, and the cap mouldings and string courses give the idea of holding up or binding together. In the North of Europe we see the steep roof, the mouldings and string courses are undercut to throw the water off the walls—each telling their tale, the one of a hot, dry climate, the other of a cold, wet climate.

Let us then take the clue from the old masters and design as they did, to suit the climate; we can then be sure we are so far in the right path.

We will have a more difficult problem to solve; we have the warm climate of Italy and the cold climate of Northern Russia, but we have the advantage of seeing how each country designed, and in being guided by Nature let us have a style characteristic of the climate and country.

All this cannot be done in a day, nor a year, nor a lifetime; no style was ever invented in so short a time; it took hundreds of years, but it was always steady progress; let us determine not to progress backward, as the Irishman would say, but let us leave the world further advanced than it was when we entered it.

* Paper read at the Third Annual Convention of the Province of Quebec Association of Architects.

DECORATION AND FURNITURE

SOME NOTES ON THE RELATION AND APPLICATION OF THE SISTER ARTS, PAINTING AND SCULPTURE, TO ARCHITECTURE.*

By A. T. Taylor.

Architecture, Painting and Sculpture, like the three graces, should be interwined in inseparable bonds in our monumental art. Each may live apart and be beautiful in itself, but the perfect life can only be consummated in conjunction with each other. Architecture, the first-born of the sisters, flourished for a while, but conscious of her needs, took under her sheltering wing her younger sisters, Mural Painting and Monumental Sculpture. Painting and sculpture apart from architecture are later growths, and I cannot but think all suffer from the severance. The earliest examples of painting and sculpture known to us were always employed to heighten the effect and intensify the functions of the architecture, and many of the finest treasures of our picture galleries and sculpture galleries to-day were originally conceived and designed with the setting of some cathedral or noble building.

Let us glance briefly, 1st, at mural painting and color as applied to our architecture, and 2nd, at sculpture and carving in the same relation.

First, of color decoration.—The love of color is natural to man. All savage people have in common the love of bright colors, and we instinctively rejoice in the poly-chromatic feast spread before us in nature, ever varying with the changing year.

Recent researches have demonstrated the fact beyond dispute that in all ages and amongst all peoples color has had an important place in architecture. Hiltorph in his investigations in Sicily and the Acropolis of Selinas and other temples, found abundant traces of rich color on all the buildings, and recent investigations in Greece have abundantly proved the liberal use the Greeks made of color on the exterior of their temples, etc. The custom also prevailed extensively all over France in the middle ages and during the period of the Renaissance, but gradually declined in the reign of Louis XIV. Viollet le Duc, the late eminent architect and antiquarian made a careful examination of Notre Dame cathedral at Paris, and found unmistakable evidence that a large portion of the facade had been radiant with color, and even in England many of the cathedrals there show also remains of colour, but the climate has dealt too rigoronsly with them to leave much evidence.

Under the sunny skies of Italy, to this day, they revel in the most beautiful colors on the outside of their buildings. The Duomo at Florence and the older Baptistry are glorious in colored marbles, and not a little of the indescribable beauty and loveliness of Giottos' Tower there, is due to its color as seen under soft Italian skies. St. Marks at Venice, both inside and out, is rich in colored marbles and gold mosaics, mellowed by time into beautiful hues.

Somehow when we moderns took to borrowing Roman orders and architecture the dead forms only were reproduced and the rich color was forgotten.

The monotony and dullness of the average streets of cities are very depressing. Some years ago in London the average fashionable house had a dingy colored compo-cement front, and the back was too dreadful to think of; then there came a reaction, and armies of painters appeared, and lo! the fronts of the houses blossomed out in claret color, and sage greens, and blood reds, and mustard yellows, and other colors hard to give a name to; and, although in some cases presenting a somewhat incongruous and piebald appearance, were yet infinitely better than the suicidal looking fronts of old. The next stage was better still—that of using honest material of natural pleasing color which would withstand the smoky atmosphere. So terra cotta and tile work and warm colored stone were and are used.

In New York there was a brown stone period when a man could not show himself in society unless he lived in a brown stone house, and so streets and terraces of brown stone still shadow our spirits. New York and other cities had also their white marble period, when to live in a marble house was thought the acme of bliss, and so leprous looking erections crept out and reared their heads in the streets, and to come nearer home, a cut limestone house was considered amongst ourselves as the sign of eminent respectability. Now, however, more pleasing arrangements of material and color are being introduced, red and mottled plum colored bricks and red and warm creamy colored stones meet the eye in all the newer quarters of cities, and in combination with the green of the trees and grass, make pleasant symphonies. We do not want the exterior of our houses to be like harlequins, but neither do we want them to be like quakers or grey nuns.

In passing I would just mention the beautiful majolica or faience work of Luca della Robbin which glows from so many of the facades of the Italian churches. They were chiefly figure work of a religious nature,—holy families, virgins and child saints, etc., but so beautifully modelled and such rich colors burnt in and glazed so as to be almost imperishable. The secret of the art was so well kept by the Robbin family that it died with them and we have been unable to get the full brilliancy of all the colors, but a recussitation of this decoration in some such form would seem to be very suitable to the conditions of modern times.

For the interior decoration and embellishment of our best buildings we have many noble examples in the ancient fresco work still left to us in such buildings as the Sistine Chapel at Rome in the Loggia and Stanzes of the Vatican in the Campo Santa at Pisa, and in numerous churches and public buildings. In these the drama of human life is portrayed in all its lights and shades, whether religious, secular or classical, and I can conceive of no grander or nobler way of applying mural painting to a noble structure than by such representations, embodying if in a sacred edifice—a nation's religious beliefs and aspirations, and—if in secular buildings—a nation's history and noble deeds of her sons. In our modern work there has been far too little of this—the highest and noblest of ornamentation. We have a little of it in some of our churches and public buildings, more or less satisfactorily carried out. Many examples will occur to you all, such as in Paris in the Pantheon, in the Hemicycle of the Beaux Arts, etc. In London, the Houses of Parliament have been partially treated in the same way, where the Death of Nelson and the Victory at Waterloo are appropriately painted on the walls, and also where scenes from the stirring history of England in the time of Cromwell and the Charles's line the corridors, to keep ever before the eyes of the legislators the lessons of the past. In the Manchester town hall the interior of the walls are being decorated by those gifted geniuses, Frederick Shields and Ford Madox Brown, with subjects from the history of that city. In the Parliament Houses at Ottawa there is a picture commemorating the Confederation of the Dominion, painted by Mr. Harris of our city, a few years ago. This is, however, a framed picture. A series of such would be the most fitting decoration for our legislative halls that I can conceive of, and if instead of being pictures in frames they could be incorporated in the decoration of walls, either in fresco or other other work, they would be better still. In the Bank of Montreal I had the good fortune to be able to formulate some such scheme on a small scale.

There I endeavored to represent in a permanent form scenes in the early history of our country, such as "The Landing of Jacques Cartier at Montreal," "Champlain at the Chaudiere," "La Salle setting out for the discovery of the North West," etc. Our City Halls and Courts of Justice ought to furnish wall spaces for appropriate decorations of this kind, and there is heroism in our own history and in the present day as worthy to be immortalized and handed down to posterity as any in the days of old. There are triumphs of peace as well as of war, victories of the pen as well as of the sword, that are waiting for worthy pictorial representation in all the arts.

We come now to our 2nd and last division of our subject—Sculpture and Carving in relation to Architecture. Certain writers have fallen into the mistake of claiming too much for sculpture on our buildings, declaring that it is the "soul and voice of architecture." With these writers I cannot agree. Were all painted decoration and sculptural ornament omitted from a building, it were possible by reason of perfect proportion, magnificent mass, grace of outline, subtle combination of light and shade, beauty and refinement of mouldings, and balance of parts, to produce a building that would impress all beholders. Of this we have many examples in early ancient work. On the other hand, however, there is no doubt that appropriate sculpture and painting lends an additional charm to the work, lifting it up to a higher plane of excellence and symbolizing in a higher and more tangible degree the aspirations, hopes, faith and morals of the community. In the use of sculpture on our buildings it has always seemed to me that the purpose and object of the building to be thus ornamented should always be kept in mind.

Thus on a church, or other sacred building, the sculptured ornament should have direct reference to sacred subjects and be largely symbolical of the faith, the hopes, the history and the bright examples set before us. You all probably have seen buildings intended for sacred uses that you could not tell from a music or concert hall. If the building is a town hall, in its ornament it should have reference to civic matters and such as affect the common weal; if a court house, it should have ideas embodying law, justice and such like. If the building is a school or college or place of learning, then appropriate symbols and mottos and the names of great men distinguished in special branches of study should be inscribed upon the walls; if a picture gallery, the choice of sculpture and suitable decorations drawn from art is obvious; if a public library and reading room, then English literature is a perfect storehouse of suggestions; if a private house, domestic panels and ornaments of a homelike nature and inscriptions add greatly to the interest. It is no small part of the attraction and charm of the old houses of Edinburgh, Chester, London, etc., to spell out those legends and mottoes and texts that our ancesters loved to carve in stone over their doorways, etc. What an added charm the streets and buildings of our cities would have if this distinctiveness and appropriateness of sculptured ornament and features could only be carried out.

We have many fine examples of what I am trying to advocate, in th

*Paper read at the Third Annual Convention of the Province of Quebec Association of Architects.

splendid monuments of the past which remain to us. Foremost amongst these must be placed the grand Parathenic procession of the frieze of the Parthenons, much of which under the name of the "Elgin" marbles can be studied in the British Museum. Then comes the Giotto Tower at Florence, so ably interpreted to us by Ruskin in his "Mornings in Florence." There are 27 panels in sculptured stone round the base, forming a unique series, beginning at the Creation of Adam and going on to represent the exact sciences and the arts, all admirably conceived and worked out, and would well repay hours of study. Just across the way from the tower, a few steps brings us to the famous gates of the Baptistry by Ghiberti, that Michael Angelo said were fit to be the gates of paradise. The whole doors are divided up into panels, which are covered with bas-reliefs of Bible subjects, from the creation to the time of Solomon. In the Cathedral of Orvietto, the portals are also covered with bas-reliefs of Scripture Subjects. In the Doge's palace at Venice, the well-known "Judgment of Solomon" and the other sculptures will readily ocurr to all. Notre Dame at Paris and the Saint Chapelle have their portals rich with subject sculpture. But it is at Amiens Cathedral that we will find the most complete example of suitable ornament, magnificent in its conception and splendid in its execution. So complete is it that Ruskin has called these western portals the Bible of Amiens. The workmen got *three sous* a day for carving these immortal sculptures. We give some of our workmen $3 a day for squaring the stone. Imagine our churches glorified with such work! What a delight to examine and study them!

In modern work we have also many interesting examples of appropriate sculpture. In the Albert Memorial at South Kensington, London, you will remember that the base or podium of the monument is surrounded with sculptured figures in alto-relievo of the great masters of all ages, in art, literature, science and music, forming a charmingly interesting procession of the genius of the centuries, and at the corners are beautiful colossal groups symbolical of the four quarters of the globe. In the Natural History Museum at Kensington there are rows of sculptures of extinct animals and up the moulding of the arches monkeys are climbing in a very spirited manner; and to come down to buildings for more common-place uses, I noticed a baker and confectioner's place in Westminster with some excellent panels of terra cotta work representing the different processes through which corn passes before it becomes bread. Why should each building erected for a special use or manufacture not have some expression of its purpose in carved or sculptured form? Our streets would become a museum of art to which future generations would come and find much pleasure and profit in. As we have received noble heritages from our ancestors, so future generations will justly expect a noble heritage from us of good, beautiful and true architecture in its completest form, making use of the sister arts, painting and sculpture, to clothe great clerical truths in immortal shape.

The limit of time at my disposal will not allow of my going more deeply into the subject; and I can only hope that these few notes may lead to useful discussion, and awaken thought and attention to this phase of our beloved art—the advancement of which is so dear to all of us.

PERSONALS.

At the recent opening of the Victoria College building in Toronto, a suitable tribute was paid to the memory of the designer, the late Mr. W. G. Storm.

Particulars have arrived from Paris showing that the death of Paul Peel, the artist, was due to hemorrhage of the lungs, and that he was ill only eight days.

Mr. W. A. Langton, Registrar of the Ontario Association of Architects, has removed his office from the Merchants Bank Building to the Canada Life Building, King street west, Toronto.

We are pleased to hear that Mr. W. B. Cherry, manager of the Adamant Mfng. Co., Toronto, who has been incapacitated for some time past by a severe attack of rheumatism, is rapidly approaching convalescence.

Mr. Wm. MacClennan, an architect by profession, who attained a world-wide reputation as a Scottish dancer, died under a surgical operation in Montreal on Oct. 30th. He had resided in Montreal for three years and was held in much esteem.

Mr. A. E. Husbands has opened an office for the practice of architecture and civil engineering, at Cookshire, Que. Mr. Husbands has been appointed engineer of the proposed new water supply and sewerage systems of that town. He will be pleased to receive catalogues, etc., from supply firms.

The firm of Knox & Elliot, architects, Toronto, has been succeeded by that of Siddall & Baker, composed of Mr. J. Wilson Siddall and Mr. Frank Baker. The firm has removed to new offices in the Janes Buildings, corner of Yonge and King streets. Mr. Baker is the first Canadian student of architecture to pass the examination of the Royal Institute of British Architects.

This is a good rule for preparing an advertisement: Write it out, no matter at what length, putting in everything worth saying; next, examine it critically, with the purpose of ascertaining how many words can be stricken out without injuring the sense. Nothing need be said for ornament. Write plain and honest facts, claim nothing but what is strictly true, and be sure to claim all that is true. Consult taste rather than space in the use of display.—*Printers' Ink.*

SANITATION AND LIGHT

THE PLENUM SYSTEM OF VENTILATION AS APPLIED TO THE NEW SURGICAL BUILDINGS OF THE MONTREAL GENERAL HOSPITAL.*

By A. C. Hutchison.

The necessity of efficient ventilation in buildings where large numbers of persons are congregated together will be readily admitted, but in no class of buildings is it so essential as in hospitals, where though the occupants are few in number and the air space allowed to each person is far in excess of what can be allowed in a hall, school, church or theatre which are only occupied for a few hours at a time, there is on the other hand a constant occupation of the wards in an hospital and the necessity for a larger supply of fresh air to a person in sickness than to one in health.

The requirements of the human body are such that when in a state of health a constant supply of fresh air is needful to maintain it in that condition, and that when diseased and weakened by sickness the necessity for an abundant supply of pure air is much increased and in many cases absolutely necessary as a means of restoration to health.

Ventilation may be briefly stated as the process by which the air in closed and inhabited rooms is maintained as nearly as possible at the same standard of purity as the air surrounding the room or building, and only the processes by which this is most successfully accomplished and without causing draughts may be considered efficient.

So much has been said and written on the subject of ventilation, that it is needless for me to describe the composition of the air we breathe, and how the proportions of the gases which compose it are changed in the process of breathing and become impure. Of the various impurities which are found in the air of inhabited rooms, carbonic acid is the most common, and when it is present in the air in a proportion exceeding ten parts in ten thousand we are informed by sanitarians that the air is unfit to dwell or sleep in; the object, therefore, of any process of ventilation, is to introduce such a volume of fresh air into inhabited rooms as will keep the percentage of this gas at the minimum. Authorities on sanitation claim that to preserve the lowest standard of purity one thousand cubic feet per hour, for persons in health is required, while in the case of sick persons the supply should be from two thousand to four thousand cubic feet per hour. In countries of milder and more uniform temperature than we experience, the supply of such large quantities of fresh air to inhabited rooms is not so difficult a problem as it is with us where we have a range of from one hundred and ten, to one hundred and twenty degrees in temperature between the extreme cold of Winter and the heat of Summer, and where for nearly seven months in the year our buildings have to be artificially heated. Where large volumes of air have to be introduced into our buildings during the winter season, the difficulty is much increased by the means which we take to exclude the cold (and at the same time fresh air) by doubling our doors and windows and carefully closing every crevice by which fresh cold air might find entrance. Being thus compelled by the rigor of our winter temperature to prevent the flow of fresh air into our rooms by natural channels, it follows that if a large supply is to be introduced it must be in such a manner that it will not cause discomfort to the occupants.

The problem which presents itself when we are called upon to provide efficient ventilation for any building in the winter season is, how can a large supply of air taken from the outside of the building, at a temperature from freezing down to 20 or 25 below zero be introduced into a room that is almost hermetically sealed, in such a manner as not to cause discomfort by draughts or to lower the temperature of the room below 65 degrees.

It is evident that in solving this problem two conditions must be complied with: first, that the supply of fresh air shall be abundant, and second, that it is heated to a proper temperature. It therefore follows that ventilation and heating are so intimately connected together that we cannot consider the one without the other. The solution of these conditions has caused many methods to be devised, some simple, some complex, and all capable of being divided into two classes, which may be distinguished as Natural Ventilation and Artificial Ventilation.

Under the Natural Ventilation we may class all those methods where no special appliances are used to cause movements in the air and where such movement depends solely on natural forces such as may be obtained by the

*Paper read at the Third Annual Convention of the Province of Quebec Association of Architects.

difference in temperature between the air in the room to be ventilated and the air outside, or by draughts caused by heated flues, or by the force of the wind applied either to forcing air into or exhausting it from the place to be ventilated.

Under Artificial Ventilation we may class all the appliances which depend upon mechanical contrivances for furnishing the force required for causing movements in the air, and also the many kinds of furnaces or heaters, where such movement is caused by the rarefication of air passing over heated surfaces.

I think it will be admitted that while Natural methods of Ventilation may be tolerated for ordinary dwellings, or for other buildings where there are but few occupants, that for buildings occupied by large numbers of persons, such as schools, halls, churches, theatres, hospitals, etc., where a large supply of fresh air is a necessity, that they are utterly inadequate and not to be depended upon, and that for such buildings some artificial method of ventilation is a necessity.

During our winter season, where there is a difference between the temperature of the air in inhabited rooms and that outside of from forty to one hundred degrees, it is evident that any method of Natural Ventilation will be insufficient where the admission of fresh cold air direct from the outside into a room has to depend upon the opening of doors and windows, or upon Tobin tubes, or any other means by which it is admitted direct without heating, and I think that it will be admitted that where the extraction of vitiated air has to depend upon the draught of flues, or upon the force of the wind acting upon the ejectors or cowls, of whatever form they may be, that they are not in all cases to be relied upon.

For any building to which a large volume of fresh air has to be supplied and then extracted after it has served its purpose, it is evident that some method must be adopted that will be independent of the wind or other natural forces, and that combined with that method must be some means of heating the air to such a degree as will not cause discomfort to the occupants. The many different appliances devised for effecting this twofold object may be divided into three classes.

First. The Plenum System, by which air is forced into the room to be ventilated by the means of a fan operated by steam or other power, the air so forced being warmed by coming into contact with steam-heated pipes or other heated surfaces.

Second. The Exhaust System, by which the air of the room to be ventilated is exhausted or sucked out by the aid of a fan, and fresh air which has been previously warmed is drawn into the room.

Third. Those in which the air is warmed by passing over heated furnaces and then flowing naturally into the room.

I do not here intend to enter upon a discussion of the merits of the different methods I have mentioned as the adoption of either will depend upon the character of the building to be ventilated and the uses to which it is to be applied. It may, however, be of interest to you to explain as briefly as possible the practical application of one of these methods to a building which I was commissioned to erect during the past year, and in which the method adopted has I believe been applied for the first time in the city. The buildings to which I refer are the new Surgical Pavilions of the Montreal General Hospital. (The system of ventilation here referred to is illustrated elsewhere in this number of the CANADIAN ARCHITECT AND BUILDER). These buildings consist of a group of three distinct buildings, an amphitheatre and two pavilions connected together by corridors. The amphitheatre building is about 84 feet by 43 feet and two stories high above the basement; this building contains on the ground floor a number of waiting, reception and examination rooms, and in the second story a large operating theatre with a number of small rooms in connection therewith. Each pavilion is about 155 feet by 34 feet and two stories high above the basement, and contains besides nurses' rooms, kitchens, lavatories, etc., two large wards for 24 beds each and four small wards for 2 beds each, or a total of 112 beds in the two pavilions. The wards and rooms in these buildings that require special ventilation contain in all about 300,000 cubic feet of air, and the problem that presented itself in arranging a system of ventilation was how to provide a supply of air as pure as could be obtained outside of the building to the wards at the rate of not less than 3000 cubic feet per hour for each patient, without causing draughts, and at the same time warming the air to such a degree as would maintain the temperature in the building at not less than 65 degrees during the coldest weather. After careful consideration of the merits of the Plenum and Exhaust methods of ventilation, the former was adopted as being best adapted to perform the work required. For forcing the requisite volumes of air into the buildings a pair of fans, each about six feet in diameter by three feet wide, made by the B. F. Sturtevant Company, of Boston, were installed in the basement of the amphitheatre building and operated by a 28 horse power, high speed, automatic cut off engine, the revolutions of the fan being arranged for 210 per minute. From the fans, ducts made in brick work are carried along below the basement floor of each pavilion and amphitheatre building to vertical shafts leading to the several wards and rooms to be ventilated. In each of the large wards there are six of these vertical shafts, while in the smaller wards and rooms there is only one each; the air is in every case discharged from these shafts into the rooms close to the ceilings. As it was considered of importance that the air discharged into the large wards should be dispersed throughout the upper part of the room before it descended towards the beds, the shafts which are built in the external walls were arranged so as not to be opposite each other, by this arrangement a thorough mixing of the air is secured. The air supplied to the fans is taken through two windows, each 7' 0" x 4' 0" and to procure the air as free from dust as possible, these windows open into a court between the two pavilions where there is little danger from dust from the streets reaching them.

With the fans in operation at a speed of 210 revolutions per minute a large volume of air is forced into every room, a measurement made with an air meter showing the actual quantity to be about 1,182,000 cubic feet per hour. At this rate the air in each room would be changed about four times every hour, while the supply to each patient in the wards would be at the rate of between 4500 and 5000 cubic feet per hour. Any one who has had experience in conveying warm air through pipes or ducts will readily understand the difficulty that is often met with in sending an equal volume of air through two pipes or ducts of equal dimensions and similarly placed.

In arranging the ducts and flues it was anticipated that this difficulty would be met, and that some shafts would convey a greater volume of air into the rooms than others, even though they were of the same size and and placed in the same position in relation to the main duct. A test with the air meter proved this to be the case, and it was found that some openings gave double the volume of air supplied by others.

To regulate the flow of air in each shaft and make them as nearly as possible uniform in operation, a regulating valve was placed at the base of each vertical shaft and arranged so that the engineer could control the flow.

The fresh air as before described is supplied to each room near the ceiling, from whence it descends towards the floor and is thence carried away through gratings placed in the skirtings into ducts below the floors to the extracting shafts, which are three in number, one in each pavilion and one in the amphitheatre. These shafts have each an area of one square foot, to about each 5000 cubic feet in the building with which they are connected, and are carried up in brick work to about ten feet above the roofs. Each shaft contains a coil of steam pipes which may be used for rarefying the air and causing a draught at any time when the fans may not be in operation.

Wishing to avoid the placing of heating coils or radiators in the wards it became necessary to heat the air supplied to the fans to such a degree before it entered the wards as would keep them comfortable in the coldest weather.

To effect this object indirect steam radiators are employed, and the air is heated before it passes through the fans by a hot blast apparatus made by the B. F. Sturtevant Company. This apparatus consists of 7000 feet of 1 inch pipe arranged in a great number of sections, each section composed of two upright pipes fixed in a cast-iron base and connected together at the top by a cross pipe. The length of pipe in the sections varies, but in the longest it is not over 23 feet, so that however rapid the condensation of steam in a section when the air is rapidly passing over it, at a temperature of 20 degrees below zero, there is no danger of freezing. These heating pipes are placed directly in front of the fans, and opposite the windows by which air is admitted to the building, so that no air can find its way into the ducts until it has come in contact with the steam pipes and been heated. The manufacturers of the apparatus considered that 7000 feet of pipe arranged in this manner would be sufficient to heat all the air supplied to the wards and rooms, but as I was afraid that in seasons when the temperature remains at from 10 to 20 degrees below zero for three or four days at a time, it would not be equal to the work, I arranged a reinforcing or supplementary heating chamber in the basement, at the bottom of each vertical shaft, and in these chambers placed cast-iron radiators, over which the air could be forced to flow when it was found necessary to heat it to a greater degree than was possible with the fan alone. The radiators placed in these chambers were equal, in the whole of the buildings, to about 11000 feet of 1 inch pipe, thus giving a total heating surface, including the piping in the hot blast apparatus: of 3666 superficial feet, or equal to 17000 feet lineal of 1 inch pipe.

The flow of air into the wards, either direct from the fan, or after it has passed over the radiator in the reinforcing chamber, is entirely under the control of the nurse in each ward, who can regulate it by means of a valve operated in the ward. By thus having two means of heating the air, first by the hot blast apparatus, and second, by the radiators in the reinforcing chamber, it is expected that economy in the use of coal can be exercised and an equal temperature maintained in the wards during the winter months.

The Steel Clad Bath and Metal Co. of Toronto, have issued a pocket memorandum book, handsomely bound in red morocco, with the company's advertisement embossed thereon in gold.

A new building, 60x40 feet in size, has recently been erected for, and is now occupied by Messrs. R. Dennis & Son, wire and iron manufacturers, London, Ont.

The Bostwick Metal Lath Co., of 116 St. Peter street, Montreal, have issued a pamphlet containing the testimonials of a number of Canadian and American architects, to the satisfactory character of this style of lath. A sample of the material is attached to the book.

The Standard Drain Pipe Co., of St. Johns, Que., are applying to Parliament for increase of capital from $150,000 to $500,000. This company has been in existence 8 years and has already increased to 18 times the original capacity. The building covers 46,000 square feet, with 10 large down draft kilns, some of which are 28 feet inside diameter, and hold 70 tons of pipes each. They will probably double the capacity of the factory.

CANADIAN ARCHITECT AND BUILDER.

VOL. V.—NO. XII. TORONTO AND MONTREAL, CANADA, DECEMBER, 1892. { PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),

PUBLISHED ON THE THIRD SATURDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

Confederation Life Building, - TORONTO, CANADA.

Telephone 2362.

64 TEMPLE BUILDING, - MONTREAL.

Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

VOL. VI.

To mark the commencement of the sixth year of publication, the January number of the CANADIAN ARCHITECT AND BUILDER will be of special character. A number of kind friends have consented to assist in its production, and a satisfactory result is looked for.

Besides features of special interest, this number will show a considerable increase in size, and in the number of illustrations, while the copies to be printed will largely exceed those of ordinary editions.

During 1893 every effort will be made to maintain the steady improvement which has marked the history of this journal in the past. We invite the kind assistance of every reader for this object, while at the same time returning our thanks for favors past, and wishing each and all a Merry Christmas and a Happy New Year.

THE Council of the Ontario Association of Architects have made several attempts to procure a suitable design for an Association Seal and have at last chosen the one which we illustrate in the present number. This design which was unsigned, as were all the others submitted, is the work of Mr. Edmund Burke. The Council were greatly surprised when they discovered the author to be one of their number.

THE Registrar of the Ontario Association of Architects has sent cards to all the members requesting suggestions regarding matters of interest which should come up for consideration at the forthcoming convention in February. The members are also asked to contribute papers for the occasion. The Council is very anxious to introduce some new men and features into the next convention, and have to rely upon the members both for their help and attendance to make the meetings a success.

A SERIOUS omission in the new scaffold by-law is the failure to regulate for the use of derricks. Not only are the workmen in continual danger from the use of derricks, but the public also. Here was an opportunity to introduce into the by-laws of the city clauses by which all might be protected from the dangers of these great beams which stretch out far beyond the boardings that are supposed to protect the public. Several accidents occurred from the breaking of derricks during the past season, but we are apparently very slow to learn the lesson which such occurrences teach. The lives of hundreds of foot passengers are endangered by the raising of tons of material from the road by means of the heavy beam, supposed to be substantially built and upheld, and swinging across the sidewalks. It is alarming to contemplate what might be the extent of the calamity if a rope gave way or the beam broke, and there is sufficient precedent to make us careful.

THE cold weather compels attention to the heating apparatus. Now the landlord complains of the large amount of coal required at the boiler, while the tenants complain of the small amount of heat at the radiator. The best designed and most perfectly constructed apparatus will not heat the building unless it be attended to. Coal is put in the furnace to be burned, but when it is put on top of the bridge wall or on the dead-plate just inside the furnace door its burning will not do much good. The making of fire under a steam heating boiler requires experience and skill. The method of employing the man who will shovel the most coal for the least money is a mistaken one. It gives satis-

faction to none of those concerned, unless the coal dealer. It will pay owners of steam heating plants to employ competent men and pay them according to results. As a rule it will be found cheaper to keep a large building warm all night as well as all day, than to let it cool down at night, and a skillful fireman can arrange his fire so that for six or eight hours after he has left it the boiler will still make vapor enough to keep the radiators warm.

A MONEY by-law will be submitted to a vote of Toronto property owners on the 29th inst. for the purpose of raising $57,000 for Public School accommodation. The estimates of the School Board for building purposes in the last two years have been entirely struck out by the City Council. This action of the Council has certainly not worked out in the interests of the ratepayers, as will be seen from the fact that the Public School Board is using twenty-five rented rooms at a cost of about $6,000 per annum, or more than twice the amount of the interest on the money which the Board is asking for. In any case this condition cannot be remedied for at least a year, and if the by-law is defeated it will probably continue and grow worse for two or three years to come. We should be slow to believe that the Public School Board is so incompetent as to incur this large expense for rent without sufficient reason, and unless it can be shown that this is the case, the money to provide increased accommodation should be voted.

IN another part of this issue we publish a report of the second annual meeting of the British Columbia Institute of Architects, an association that has been in existence for about eighteen months, and which, like kindred associations, was formed for the purpose of improving the standing of the profession. At present this Institute is incorporated simply as a Literary Society, but means for its incorporation as a distinct professional association are under the consideration of the Council. The Institute has been active in the matter of the proper conduct of competitions, and we are glad to find that its efforts have met with a fair amount of success. It is gratifying to see how architects in various parts of the world are "taking up the cudgels" against the preposterous treatment that is everywhere meted out to the profession. Every new association formed for this purpose strengthens the hands of the individual architect wherever he may be situated, and we would strongly urge all architects wherever possible to lose no time in associating themselves together not merely for their own good, but for the benefit of the public, for the real result of such societies is *pro bono publico*, and affects them in a more important manner than it does the architects themselves.

ONE very striking difference exists between Montreal and Toronto as cities and in which Montreal has an immense advantage over Toronto. Toronto is so spread out and straggling that a heavy and continual expense is incurred in making and keeping up the roads, with water supply and police protection and other items altogether out of proportion. One of the results of this spreading out is that many an acre within the boundaries is left without an inhabitant, and while the suburbs still grow the city proper is at a standstill. Montreal is so compact, that an effort is now being made to attract the people to the suburbs. The policy of spreading out, as has been done at Toronto, has proved an expensive one, and is entirely due to speculators and wire pulling, the result being that the few speculators have gained at the expense of the public. It is high time Montreal spread a little, for the population is closely packed. The system of "tenements" (houses of four floors, two floors is a tenement with separate entrances) that prevails even in the best localities, disguises the fact of the overcrowding from the casual observer. But while the plan may seem to lessen taxation, rents are very high, the majority of tenement tenants paying far more for their two floors than people in Toronto pay for a "self contained" home and bit of garden. Consequently the attempts to populate the suburbs there ought to be easily carried out.

THE verdict given at the recent Toronto Assizes in the case of the Citizens Milling Co., Ashdown, Page and Webb against Defoe, was only what must have been expected, judging from similar cases before the English Courts. The building owned by the defendant, in which was stored merchandise and other property of the plaintiff, suddenly collapsed in February last, and the owner was sued for the value of the goods. The plea of the defendant was that the cause of the failure of the building was *dry rot*—unavoidable, and therefore he was not responsible. It has been held, however, in England, that the owner is responsible for the condition of his building as far as the purposes to which it is put are concerned, and that he should have ascertained by careful examination that all timbers were sound and capable of bearing the weight put upon them. In cases where the owner of a building that he wishes to use for a special purpose, has employed an architect to examine it for him, and the architect has certified that it was sound enough for that purpose, the owner has been able to recover from the architect in the event of subsequent failure. An architect is required to examine into the *hidden* parts, and it is generally a very risky thing for him to saddle himself with the responsibility of the soundness of construction unless he has been personally acquainted with the details from foundation to roof. In the present case the amount sued for is about $6,500.

Despite all that has been said and done with regard to architectural competitions the Corporation of Toronto has not yet learned that architects who have any respect for themselves will not send in plans unless a guarantee is given that the competition will be carried out in a proper manner. Suggestions for the conduct of such competitions have been drawn up in order to guide promoters, that they may be able to secure the best designs and work for the object in view. The notice given by the Markets and License Committee that they are desirous of receiving suggestions for the proposed enlargement of the Toronto Market show how absolutely at sea the Committee is. These gentlemen do not know how best to effect their purpose, and instead of employing some one as their consulting architect, they ask all architects to send whatever they like in any shape they choose, and the Committee, without any professional advice, will select the scheme that seems to them best. $1,000 of ratepayers' money is to be the award for the three best plans, which are to become the property of the Committee. This is but throwing away $1,000, for none but the very needy or youthful architects would have anything to do with such a competition. Again, this Committee may be entirely changed in a fortnight's time at the civic elections, and the new Committee may not be willing to carry out the ideas of their predecessors. Such things have happened before, and the probability is that anyone who did send in a plan would have all his trouble for nothing. Nearly seven months have been given for the preparation of schemes, and this will prove just so much lost time, for we feel confident that not one plan of any merit will be found waiting for the Committee to meet at the end of the seven months.

THE novel sight of a brigade of axe men engaged in chopping down poles erected by the Street Railway Company has lately been witnessed on the streets of Toronto. The City Engineer's action in ordering this to be done seems justifiable. The agreement which the Street Railway Company entered into with the city provides that the character of the construction and equipment of the system shall be subject to the approval of the City Engineer. The Company has lately acted as though its intention was to evade as far as possible compliance with this agreement. It has erected poles which would disgrace the streets of a backwoods village, and has accentuated their native ugliness by painting them a variety of colors. In many cases a brilliant red is the prevailing hue. There seems to be manifest in the Company's dealings with the city as well as with private corporations and individuals a disregard for the rights of others as well as its own promises. To get possession of what it wants now under promise of remedying in the future what is below the standard, seems to be the policy pursued. Whatever the other party to the contract may do, the Company appears to have always in mind the fact that "possession is nine points of the law." If the company intends to continue to own and operate the road, it is making a huge mistake by antagonizing public favor, and even if, as is asserted, its intention is to dispose of the franchise, the fact of its being at loggerheads with everybody must tend to lower the value of the privilege in the

eyes of intending purchasers. We refer to this matter because such conduct is calculated to increase the prejudice against which promoters of electric railways have had to contend, and thus to retard development.

IF we were asked to give a word of advice to the builder that should be of the greatest possible value to him we should say "Get acquainted with men in your own business, especially those who are frequently competing against you." We have in mind nothing of the nature of a "combine" or even of anything approaching an agreement that should affect prices. Such a proceeding in the building trade would be worse than useless, for if such an agreement as to prices were made, those who wanted to build would be driven to other places to get their work executed. But leaving out entirely the question of prices, there is a very decided advantage in men in the same business being well acquainted, because it destroys to a great extent unbusinesslike competition and encourages a healthy system in its place. There are other advantages, one of which may be given as an example. A man desirous of building a house invites bids from three or four builders. When the estimates are received he at once goes to Mr. Jones who is the lowest bidder and talks to him something like this: "Mr. Jones, you know very well that I would rather you should build that house for me than anyone else, because I know that you will do an honest job"—and so on, with as much of similar talk as he thinks poor Jones will stand. "Now Jones, you see you are not the lowest bidder—in fact there are two above you, but if you can see your way to take off something you shall have the job." Jones reasons that if the other builders can do the work for a lower price than his bid, *he* can, so he takes off a hundred dollars or so, with the result that he either loses on the transaction or comes pretty close to doing so. Now, had Jones been on good terms with the other builders, he could easily have found out whether he was really the lowest bidder or not, and the little "confidence game" that is as a fact carried on every day, would not have succeeded.

WE understand that the Council of the O. A. A. has decided upon holding the next annual convention in February, the opening day being the 7th inst. We have not as yet seen any programme of the meetings but we have no doubt one will be arranged that will be equally attractive to both town and country members. The last two conventions were very unfortunate as regards the weather, so much so that going about town was to be avoided as much as possible. It is at any rate to be hoped that the coming convention may be more fortunate in this respect, and if this could be foreseen, we feel sure that the Council could not include anything in their programme of greater interest and practical importance than visits of the whole body to some at least of the many large buildings that the city architects may at the time have in charge. This would be a feature that would commend itself very favorably to the country members, and at the same time an opportunity would be afforded to city members to see buildings they cannot help being interested in, but which from a variety of causes they have hitherto not visited. By making an early start, say between 8 and 9, one morning, a good many buildings might be seen, and more would be accomplished at the convention than if, as is generally the case, the meetings cannot be called to order till nearly eleven o'clock. We venture to suggest that one reason why members have proved themselves so lacking in punctuality in attending the sessions is that the country members at any rate have been trying to see as much for themselves of the city and some of the larger works as they possibly could during the hours of recess. No doubt there is a great deal of interesting matter read and discussed, but it is a question whether this should occupy all the time. Judging from the interest taken by all who met last year, in the visit to the Childrens' Hospital, visits to the Court House, new Drill Hall and some of the Banks already completed would meet with general approval.

AN extraordinary and dangerous move is being made to have the work on the Toronto Court House carried out by day labor. The public need to be put on their guard against such an innovation for they perhaps hardly understand the full importance of the move. Not merely is it an injustice to the taxpayers as affecting their pockets, but it is utterly impossible that a building of the size, quality and character of the Court House should be successfully and properly completed in the manner proposed. Day labor is all very well for works of a rough description, such as road making or drain laying, but the intricacies of a large building entail an amount of responsibility that we should imagine the architect and clerk of works would be very unwilling to shoulder. For two men, however skillful they may be, to undertake the superintendence of the details of ten or a dozen different trades and to be responsible for the work of 200 or 300 men, is out of the question. The time of the architect (and for this purpose he is employed) should be taken up with the elaboration of his scheme, not with ordering of material and the constant looking ahead to prepare for the next piece of work to be done on the building. We do not see how an architect can give his time to all the necessary works that day labor would involve. There is another matter to be considered—every year the *personnel* of the Court House Committee is changed, and who can say whether some future committee, without the experience that the existing committee has gained, would not decide that some other method should be employed. Prices, too, vary; wages may increase; a strike may be inaugurated by the men employed; these and a score of other contingencies may possibly arise, all of which would mean delay and useless expense. We have had enough trouble over the Court House, and the taxpayers are getting restive under the continual expense of litigation. The only safe and right course to pursue is to have the work tendered on in the usual manner and carried out by responsible contractors.

ACCEPTED DESIGN FOR OFFICIAL SEAL FOR THE ONTARIO ASSOCIATION OF ARCHITECTS.

TORONTO ARCHITECTURAL C.V.B. ORGANIZED 1889

At the first of the Club's meetings during the last month, Mr. J. Wilson Gray read a paper on the high buildings of Chicago, and the methods employed in their construction.

At the second meeting, papers on photography as applied to architecture were read by the President, Mr. A. H. Gregg, and Mr. J. J. Woolnough. These papers and the illustrations which accompanied them, will be published in a future number.

THE B. C. INSTITUTE OF ARCHITECTS.

THE above Institute, which has now been in existence about eighteen months and embraces nearly 40 members, held its second annual meeting on Friday, November 4th, 1892, at Vancouver, B. C., with Mr. C. O. Wickenden, of Vancouver, Vice-President, in the chair.

Minutes of the previous meeting having been read and adopted, the chairman read the following report of the year's work.

"In the absence of our President it devolves on me now to read to you the executive report of what has been done by our Institute during the past year. Since our last annual meeting held in Victoria on the fifth December, 1891, we have been duly incorporated, after taking legal advice as to the proper means to that effect, under "The Literary Societies Act." Of this you have had due intimation in the issue of our "By-laws and Declaration of Establishment." This course your Council considered advisable in order to give us a proper legal status.

The next action of your Council that I have to bring to your notice is one respecting competitions. Your Council felt it advisable to address the office of Land and Works of the Provincial Government respecting the terms of an impending competition for Government offices in Victoria. The result of this co-operation was the issue of the instructions doubtless seen by you all (correspondence read). Shortly before the competition designs were to be submitted, we again addressed the Commissioner of Lands and Works on the subject of adjudicators. Rumors of a possible reference of the designs to an architect of the United States induced us to take this action, and here again I have to congratulate you on the ready compliance of the Commissioner with our suggestions, two of our profession nominated by the Ontario Association of Architects having been appointed to assist the Commissioner in making his selection.

Most of you are aware that during the year a competition for designs for a new Christ Church Cathedral in Victoria, was arranged by the plans committee of that church. The conditions of this competition were considered by your Council as unsatisfactory, and several suggested alterations in the terms were made and forwarded to the secretary of that committee. These suggestions were not favorably received by them, the consequence being that very few designs were submitted from British Columbia. In consequence of the action since taken by the committee of the new Christ Church Cathedral issuing out of this competition, your Council again thought some action was necessary, and at a Council meeting held on Saturday, Oct. 15th, a sub-committee was appointed to go over the question and report. This report was passed as a resolution of the Council at a subsequent meeting held Oct. 22nd, and a copy sent the plans committee ; up to date reply has not been received from them.

These matters are referred to, to show our members to what extent matters affecting our position as architects have received our attention. Probably the most important action taken during the past year has been the attempted passage in the Local Legislature of our "Bill respecting the Profession of Architects," which, as you all know, was thrown out by the small majority of one, the time of its being voted on being late on a Saturday at the fag end of the session, with a very few members present. It is a question for your consideration whether the Act should be brought up again at the next session of Parliament or not.

Your Council at a meeting held on Saturday, Oct. 22nd, passed the following resolution having reference to By-law 6 : That in accordance with By-laws 1-6 the following gentlemen be invited to allow themselves to be nominated for election as honorary fellows : Messrs. F. C. Gamble, G. A. Keefer, H. B. Smith, W. S. Gore, Joseph Hunter, Edward Mohun. It remains with you now to adopt this report or not and if you have other nominations to make to add to the above.

I have to regret to add that one of your Council, Mr. Trimen, had resigned owing to continued ill health. At the Council meeting of October 15th, Mr. Day was elected to take his place (By-law 54)."

Upon the report being adopted, the vote was next taken for the members of Council for the ensuing year, when the following were duly elected :

President, C. Osborn Wickenden, Vancouver.

Vice-Presidents, R. Roskell Bayne, Victoria : Cornelius J. Soule, Victoria.

Hon. Treasurer, Edward Mallandaine, Sen., Victoria.

Hon. Secetary, W. Ridgway-Wilson, Victoria.

Thomas Hooper, Victoria ; John Teague, Victoria ; Alan. E. McCartney, Vancouver ; Richard P. Sharp, New Westminster ; A. Maxwell Muir, Victoria.

The gentlemen nominated above by the Council as honorary Fellows were duly elected, as were also Messrs. S. G. Curry, of Toronto, and A. T. Taylor, of Montreal, the experts appointed by the Government in the late competition.

After some further discussion on the subject of the proposed Bill respecting the profession of architects, a committee consisting of Messrs. Soule, Bayne, and Ridgway-Wilson, with power to add to the number, was appointed to consider what further steps should be taken in the matter and to report to the Council.

It was decided to hold the next annual meeting at Victoria, and the meeting adjourned.

GOVERNMENT BUILDINGS COMPETITION, VICTORIA, B. C.

Acting upon the suggestion of the British Columbia Institute of Architects the Council of the Ontario Association of Architects were requested by the Government to nominate two non-competing Architects to act as experts in conjunction with the Honorable the Chief Commissioner of Lands and Works in the Government Buildings competition. Accordingly Mr. S. G. Curry, President of the Ontario Association, and Mr. A. T. Taylor, F. R. I. B. A., R. C. A., a member of the Council of the Quebec Association of Architects, were appointed. After an exhaustive examination of the various designs these gentlemen handed in the following report, viz :—

VICTORIA, B. C., November 5th, 1892.

To the Honorable the Chief Commissioner of Lands and Works Victoria, B. C. :

SIR,—In accordance with our appointment as experts to examine and advise on the plans submitted in competition for the proposed new Government Buildings, we beg to report as follows :—

Sixty-five sets of drawings have beeen sent in by sixty-two competitors. We have arranged and carefully examined same, and have selected the following five designs to compete in the second competition, viz :

No. 19, "Brittanicus."
No. 56, "A. B. C. Architect."
No. 43, "St. George on Shield."
No. 25, "Utility and Dignity."
No. 17, "Utile Dulci."

NOTE.—These are placed alphabetically and not in order of merit.

We have selected the above as most nearly fulfilling the conditions and requirements of the competition.

We regret that we were obliged to reject several designs of great merit on the ground that the expense of carrying them out would grossly exceed the limit of cost stated in the conditions of competition.

None of the designs submitted were entirely suitable in the internal arrangements of the several departments, owing, we think, in a great measure, to the inadequacy of the information furnished to the competitors.

We would respectfully suggest that as full information as possible of the requirements as to space, and the internal working of the several departments, be furnished to the competitors in the second competition.

We are, Sir,
Your obedient servants,
S. G. CURRY,
ANDREW T. TAYLOR.

After this report had been received, the sealed envelope bearing the *nom de plume* of each was opened and the names of the successful competitors were found to be—

"Brittanicus," F. M. Garden, Chicago, U. S.
"B. C. Architect," F. M. Rattenbury, Vancouver, B. C.
"St. George on Shield," J. F. Brown, Toronto, Ont.
"Utility and Dignity," Messrs. Skillings & Corner, Boston and Seattle, U. S.
"Utile Dulci," T. C. Sorby, Victoria, B. C.

These gentlemen will be at once requested to submit a second set of designs in accordance with the terms of the competition.

The Government desire to thank the various architects who competed, and feel it is a matter for congratulation that such a large number of designs of great merit were received from which to make a selection.

W. S. GORE,
Deputy Commissioner of Lands and Works.

Lands and Works Department,
Victoria, B. C., 9th November, 1892.

OBITUARY.

Mr. Wm. Gearing, one of the best known and most highly respected builders of Toronto, died of consumption at his home in that City on the 3rd inst. Mr. Gearing was incapacitated for business for two years preceding his death. He was a native of Wattington, Oxfordshire, England, and was forty one years of age. The funeral ceremonies were very largely attended. The officers of the Toronto Builders' Exchange were present, some of them in the capacity of pall-bearers.

The product of the Ontario drain and sewer pipe factories for the tax year is valued at $360,000.

CHARACTERISTICS OF ARCHITECTURAL STYLE.

BY G. F. STALKER.

(Continued from page 56.)

About the time when Solomon was in "all his glory" (although for the temple, his palace, and other buildings erected by him he had to go outside his own kingdom for his architects and builders), the various small principalities lying towards the south-east of Europe were gradually drawing together and being cemented into one nation. There were race distinctions among those people, strongly marked and even antagonistic, and so long as they remained apart from each other, the probability is that they would have become absorbed into one of the more powerful nations to the east of them, and so have lost their individuality or have lived their allotted time in this world in a condition of mediocrity. In any case they would, in all likelihood, have left no distinctive landmarks behind them. But after many bickerings among themselves, in which (like many other great nations since that time) they played a military game of see-saw, they found that they had so many interests in common, that by degrees they became fused together into one homogeneous nation. It was well for the world in general, and for art in particular, that this great event happened. The result of the fusion of the Hellens, the Spartans, the Dorians and others, has been a source of wonderment for the world ever since its accomplishment. Rapidly, as nations move, the principalities became unified, and then they seemed to be in a hurry to make an everlasting impression on the pages of the world's history ; for, as Fergusson puts it, "all those wonders of patriotism, of poetry and art, for which Greece was famous, crowded into the short space of a century and a half, is a phenomenon the like of which the world has not seen before, and is not likely to witness again."

But, be the time of Grecian supremacy in the world long or short, this fact remains, that in Greece and that part of Asia Minor immediately under the rule of the Greeks, architecture reached its highest stage of development in ancient times ; and, in what we call classic architecture, nothing has been produced since their time, which, for beauty, for purity, or even utility, can surpass or equal the works of the Greeks. That they drew largely from Egyptian and Assyrian sources for their designs is abundantly evident, particularly in their earliest works. But in their hands everything, borrowed from whatever source, underwent a process of improvement and refinement, so that when we come to the time when they were at the zenith of their power, they had created a style of architecture distinct from anything that existed before—peculiarly Grecian, and having in it principles upon which succeeding styles were based.

The Doric order (which was derived from an Egyptian source), was that most largely used by the Greeks in their temple and monumental buildings. At first they gave to its proportions more solidity and massiveness than was found in the Egyptian columns from which it was borrowed, and that to such an extent as to border on clumsiness. But such examples are so few in number, that we may conclude that they quickly saw their error and set about correcting it. At the same time they had no hard and fast code of proportions of the various parts of any of their orders by which they worked. The arbitrary rules which are sometimes taught in schools and academies as belonging to this and that order, were drawn up by Sir William Chambers on no higher authority than his own. But in the Grecian buildings still in existence, there are no two examples in any order which are in all respects, either as to proportions or detail, exactly alike. They have a family resemblance to one another and nothing more. It is acknowledged, however, on all sides, that the Parthenon is the most perfect example of the Doric order. And this building is so inseparably linked with Greek art that one never thinks of the one without the other coming to mind. In outline every detail is of the very simplest, and at the same time the most effective form, bearing to each other such admirable proportion that the whole is absolutely faultless.

But the Greeks did not depend on the strictly architectural features of the buildings alone for their beauty, for with their exquisite detail and perfect masonry they united the sister arts of sculpture and painting. Without these, indeed, their buildings would have been somewhat bald, and certain parts of them meaningless. But these arts formed an essential part of the design, and were intended to, and did, give life and dress to what would otherwise have been very simple structures. Many of the ornaments which in some late examples were carved, were in the earliest buildings executed in color. The sculptures also were relieved by colored backgrounds, and the figures themselves were sometimes painted. It will thus be seen that a Greek temple, when first erected, required an harmonious combination of the arts of architecture, painting and sculpture, to complete the composition.

The Ionic order was less dependent upon sculpture than the Doric—that is to say, as far as the human figure was concerned. The form of the column was more attenuated and the whole entablature much compressed. The details were also more enriched by carving, and so the necessity for sculptured work was greatly lessened, or altogether dispensed with. In this order the columns are provided with moulded bases, and the chief features of the capital (as indeed, it is of the whole order), is its bold volute, which no doubt was derived from an Assyrian source. The same minuteness and elegance of detail, and the same finished masonry were used in this order as in the Doric, though it lacks that force and vigor which is so manifest in the latter.

Towards the decline of Greek art a third order, the Corinthian, became dominant, although it was never used in buildings of first importance. Its base was more elaborately moulded and its capital more richly carved than the Ionic order. Its entablature was also bolder and better suited to the introduction of sculpture.

Such are the three orders of Greek architecture which are easily distinguishable by their capitals alone. The Doric has a square cap or abacus, with a rounded moulding underneath it ; the Ionic has the volute ; and the Corinthian has the bell of the cap richly foliated. The poet Thomson in his "Ode to Liberty," says of Greek architecture :

"First unadorned
And nobly plain, the manly Doric rose ;
The Ionic then, with decent matron grace,
Her airy pillar heaved ; luxuriant last,
The rich Corinthian spread her wanton wealth.
The whole so measured true, so lessen'd off
By fine proportion that the marble pile,
Formed to repel the still or stormy waste
Of rolling ages, light as fabrics look'd
That from the magic wand aerial rise."

But besides the striking distinctions in the capitals of the three orders, it must be observed that the most characteristic feature of Greek architecture is that of horizontality. The general squareness observable in Grecian buildings gives an indication of strength and solidity ; the long unbroken lines of entablature are suggestive of repose ; while the mouldings, consisting as they do of a variety of flowing curves, soften the severity of the lines and add grace and beauty to the whole.

Though Rome was founded as early as the union of the principalities of Greece, it passed through several centuries of its existence before erecting any buildings calling for notice, or that in any way were distinctive as regards architectural style. Conquest and the accumulation of wealth seem to have been the motive power of Rome as a republic. During this time neither art nor letters received much attention or encouragement from this restless, fighting, conquering people. But after the great powers of the world had been subjugated, and made tributary to Rome—when she became the capital of Europe and mistress of the world—then during a period of comparative peace she became the lodestone that drew to herself all the learning and the art that had flourished in other countries. Art treasures in immense quantities, captured in her successful wars, were poured into her lap. Artists from Greece and Asia and Egypt flocked into the imperial city in great numbers, and then sprang up in rapid succession innumerable buildings of much larger dimensions, of more costly adornments, and for a greater variety of purpose than the world had ever known.

The claims of the business life of a busy people had to be considered, and so architecture spread its wings, and instead of being confined to temples, palaces and tombs, it took within its wide and friendly embrace buildings of every description. Baths, market-places, theatres, monuments, aqueducts, bridges, villas, gateways—anything in short that was built was by them treated architecturally. They seemed to consider that what was worth building was worth building artistically. Architecture

under the Romans was consequently more varied as regards its design, and more cosmopolitan in its application than it was in the hands of any of the nations before their time.

There is, however, less distinction between Roman architecture and Greek than there is between the latter and its antecedents. The same orders were used, but in an enriched form. The Corinthian order was certainly improved by them, and the composite order is, after all, only a modification of the Corinthian. To the Romans, however, must be accorded the credit of introducing the semi-circular arch both as a constructive and decorative feature. They were not the inventors of this form of arch, but they applied it in such a manner as to make it a characteristic feature of their style of architecture and explode the ideas that had formerly existed as to its structural soundness.

Just as the columns were enriched, so also was the entablature. Wherever carving could be applied it was done, and where color could be introduced by the use of precious stones or metals no other mode of coloring was adopted. From first to last experience was the order of the day at Rome. But in all their work there is a sort of manliness visible, and no problem of structural difficulty ever presented itself but to be overcome. Roman architecture has also this interest attached to it, that it broke away from the horizontal lines which had ruled in all previous styles, and established a point of departure which led up to the adoption of vertical lines as the leading principle in succeeding styles.

A REPLY TO MR. BOND'S LETTER.

Editor CANADIAN ARCHITECT and BUILDER.

SIR,—In reply to young Mr. Bond's communication of 22nd Oct. last, in reply to mine which you previously published, commenting on your correspondent's mis-statements, permit me to state that I, as inspector of Mr. Tuckett's building, *ought to know* when the carving was done on it, and I most emphatically deny that any was executed until long after your correspondent's spiteful notes had been forwarded to you.

Herewith I send you a tracing taken from the original drawing, and request you to submit it to the criticism of any architect to say if not only the skilled sculptor, but the merest schoolboy in architecture, would not be justified in holding it up to ridicule.

Yours, &c.,

JOHN WATSON,
Inspector of Buildings, Hamilton, Ont.

[As no useful object is likely to be attained by continuing this correspondence, we decline to allow it to proceed further.—EDITOR C. A. and B.]

"CANADIAN ARCHITECT AND BUILDER" COMPETITION FOR A CITY HOUSE.

THE CANADIAN ARCHITECT AND BUILDER invites competitive designs for a city dwelling, to cost $15,000, and to be erected on a lot 30 × 125 feet. The lot will face the narrow way, south, long way, east. The main west wall of the building must stand on the party line between the lots, and the main east wall must come upon the street line. There is to be no enclosed area for lighting.

The building is to contain three clear stories above ground, to be constructed of stone, or of stone and brick, with sloping or flat roof. No overhanging tile or shingle work will be allowed.

The entrance may be on either front, at the option of the designer.

The number and location of rooms and the purposes which they are to serve is left to the judgment of the designer.

Competitors will be required to furnish plans of basement and three upper stories, and elevations of south and east front. Perspectives may be submitted at the option of the competitors. Floor levels must be marked on the side of the elevations.

This competition is restricted to architectural students and draughtsmen in Canada.

Drawings must be made on sheets of heavy white paper or bristol board, 14 × 20 inches in size, and must be drawn sufficiently coarse to allow of their being reduced to one-half the above size. Drawings must be made in *firm, strong lines*, with *pen* and *black* ink. No color or brush work will be allowed. Each drawing must be marked with the *nom de plume* of its author, and the author's name, *nom de plume* and full address, enclosed in a sealed envelope, must accompany each drawing sent in.

Drawings must reach the office of the CANADIAN ARCHITECT AND BUILDER, Confederation Life Building, Toronto, on or before the 4th of January, 1893. The right is reserved of publishing any drawing sent in. Drawings will be returned to their authors within a reasonable time after the competition is decided.

The first premium will be $15, and the second, $10.

The merits of the designs will be decided by a committee composed of three members of the Ontario Association of Architects, and their decision will be final.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT and BUILDER).

It has been decided to hold monthly meetings of the Montreal members of the Province of Quebec Association of Architects. On the evenings set for the meetings the members will dine together at the St. Lawrence Hall, and go direct from thence to the meeting in the Association rooms on St. James' street. The first of these meetings took place last week, on which occasion a paper on "The Functions of Truth in Art" was read by Mr. A. T. Taylor, F. R. I. B. A. The reading of the paper was followed by an interesting discussion. It is the intention also to revive the classes for students, which were attempted to be established last winter. The Montreal members of the Association have evidently set their hands to the accomplishment of practical work on behalf of the Association and the rising generation of architects. They deserve and should receive the most cordial assistance of every member of the profession.

THE FUNCTIONS OF TRUTH IN ART*

The foundation of art to be enduring must be laid in what Carlyle calls "The eternal veritie." Of these one of the greatest is Truth.

There can be no real permanent art without truth; and in all art there must be beauty, and these two are inseparably joined, for in all truth there is beauty and in the highest beauty there must be truth. If we study the great architectural epochs of the past we will find this truth recognized and given full expression to in their greatest and noblest memorials and achievements; and just in proportion as truth in construction and design was ignored so degeneracy in vigor and life set in. No nation and no individual can afford to neglect truth, whether in ethics, poetry or in art. It must be placed like a precious jewel in the breast-plate, unsullied and undimmed by compromises or subterfuges.

In painting—the most intangible of the graphic arts—the rules are somewhat less abstract and definite than in architecture and sculpture, but truth governs none the less. The great artist, to be sculptor, architect or painter, must be born; he is like the great poet, the great musician, the great prophet, he has a divine mission; profound thoughts have been whispered into his soul to deliver to his fellow men; and therefore, because we cannot always make them fit in with our preconceived ideas, we must not be too hasty in condemning them. Revelation comes to us with many voices, and thoughts in varied channels. Were these not in part sometimes incomprehensible to the average run of humanity, then would the artist not be worthy to be called "great" and become commonplace.

Nature is the fountain of art, the quarry from which art's achievements are obtained; but Nature has to be interpreted, and in the interpretations men may err. As miracles have been said to be not violations of natural law, but the action of a higher law of which at present we may be ignorant, so certain phases of art, although apparently not true to Nature as we see it, may be entirely in sympathy with the deeper truths of Nature that we ourselves may not, as yet, have discovered and appreciated. Truth on its finite side is not absolute but relative, and therefore pre-Raphaelitism, Romanticism, Impressionism and many other isms have visions of truth in them important for mankind to know.

A picture may be truer to Nature and give one the very spirit of the scene although, probably, it may be a poorer imitation of the features of the landscape and of the ordinary color, than one which may be very correct in its lineaments and chromatic scale. Turner in many of his pictures took great liberties with Nature, but he has given us such an insight into the versatility of Nature, such atmospheric effects, such luminousness, and such a revelation of possibilities, that no one that I know of has ever surpassed and few equalled.

Have we not all seen a portrait in which all the features were correctly drawn and yet the whole effect wooden and inexpressive, and have we not seen another, it may have been but a rapidly dashed off sketch, roughly done, and perhaps not very correct in drawing, yet because there had been caught the spirit of the man, some special characteristic—THE MAN, not the outer shell—we felt at once it was the truer and better of the two. Truth is not merely imitation; were this so, then photographs as being most nearly correct transcripts of Nature would be the best and would take the place of paintings. Even leaving out the question of color you expect something more in a picture than in a photograph. You all remember the well known story of Zeuxis and Parrhasino who had entered into a friendly competition to paint the best picture; Zeuxis painted a bunch of grapes which looked so natural that the birds came and pecked at them, and when he called on his rival to draw aside the curtain to show his picture the found that the curtain itself was the picture. Zeuxis confessed himself beaten,

* Paper read by Mr. A. T. Taylor, F. R. I. B. A., R. C. A., before the Montreal members of the Province of Quebec Association of Architects.

saying, "I deceived the birds, but you have deceived an artist." You also remember the story of the painting of the fly by young Giotto on the nose of a figure his master was painting, which was so lifelike, that to the delight of the pupil, his master tried to brush it away with his hand. Mere imitation, however clever, is not the highest form of art, it is a trick that can be learned, but it is the mind of man impressed on the canvas that gives it value. By some strange perversity we have rigorously demanded Truth in speech and action but allowed it sadly to go by default in art. The need of truth in art is paramount and I should like to emphasize it still more and say that art will flourish first in proportion as faithful and honest methods are employed and truthful and honest thoughts impressed on the work.

Art in all its phases should be interesting to us as architects; as I hold very strongly that an architect should be an artist as well as a constructor; but it is natural that it should be of special interest to us in its relation to architecture and the applied arts. In everyday art this question of Truth presses most closely to us. Our houses, our streets, our surroundings, are with us all the time and unconsciously influence us; and if these are not instinct with truth we shall make our own Nemesis to bring on our own punishment? I am happy to think that the crusade against shams, largely influenced by the powerful and brilliant writings of John Ruskin, has resulted in the abolition of many of the worst, but they are hard to kill, and too many are still left to us and need rooting out also. It seems to me that a fundamental rule is this: Always let a thing look what it is, and do not make it try to look like something else. Iron and steel are great friends to us, but they have often turned to be our enemies, by reason of our inability to use them rightly; and, I am sorry to say, they are responsible for much questionable work; the facility with which we can bridge wide spaces, carry heavy walls over voids, and generally disregard the disposing of walls, piers, etc., above each other, has led to the violation of some of the elementary principles of construction. We have also to thank the same material for making it possible to construct those enormous lofty buildings in which Chicago has the unenviable notoriety of taking the lead. I cannot but think that these will, before long, come to be looked upon as stupendous blunders; the utter disproportion of scale and mass to their surroundings, the fatal disturbance of harmony and proportion to the environment, to say nothing of the disturbing sense of feeling that what is visible of the slim, lower stone and brick piers, is manifestly and apparently inadequate to support the enormous superstructure without the aid of iron or steel supports behind the piers. In many modern buildings the outer walls help little in the construction, and are merely enclosures and could be removed without affecting the stability of the floors or roof. I cannot but feel there is a grave danger looming ahead for many of the skeleton framed buildings in which the iron or steel uprights are built into brick-work for fireproof purposes, and when in time rust and decay will set in without the possibility of detecting or remedying it until it makes itself known by sudden and fatal failure.

In speaking of Chicago one's thoughts involuntarily turn to the White City which has been rapidly rising in its midst for the World's Fair. The material called staff, made of plaster, jute and water, which has been employed for most of the exterior, has proved such a pliable and adaptive material for temporary work that there is a great danger that it will be adopted for more permanent structures, and just as we are congratulating ourselves that we have got rid of "compo" and stuccoed fronts, which so long held horrid sway, to the utter degradation of all true art, we will be threatened with a return of the old pernicious and objectionable material, only perhaps a little better in quality. We have to guard against the lack of truth in construction and in outward finish. If we can only afford to build a common brick house let us try to bring out the utmost capabilities of the material in simplicity, and not cover it with plaster and line it to look like costly stone, until the miserable subterfuge is evident when the plaster begins to fall off. If a plaster finish is desired, then let it be treated as plaster, and stamp patterns upon it or leave it rough cast and honest, but do not try to make it look like stone when it is not.

Motives of economy and narrowness of view on the part of clients have been to blame I am afraid for the extensive use of galvanized iron in cornices and such like—so detrimental to the dignity and truthfulness of a building in the long run, and it is for each of us to consider seriously how far it is right for us to pander to this. It is a phase of architecture largely peculiar to Canada, and hardly one that we would care to proudly hand down to posterity as our contribution to a noble national style of architecture. If we cannot afford doors of hardwood, let us have them of pine, honestly varnished or painted, but do not let us grain and paint them to imitate oak or mahogany or maple. A thousand times better to have a plain thing that is honest and truthful than an elaborate thing that is a lie. No true art can exist where such things prevail, and we must remorselessly root them out. Until quite recently the grained roof of Milan Cathedral was painted with imitation tracery work to look like perforated stone, and deceived many people. Within the last two or three years, however, this deceit has happily been painted out, and it is the intention to decorate it with frescoes of sculptured subjects in an honest genuine manner.

At Abbotsford, Sir Walter Scott had his paintings fixed to the walls and frames painted round them with sham mouldings and ornament, shaded to imitate relief work, and this is a very common form of deceit. You will see it even in churches, where surely, if anywhere, truth should be absolute in its sway. There may still be seen entrance halls and staircases of some houses, the halls hung with papers to imitate marbles of all colors and kinds—Siena, dove, purbeck; generally, part of it is coming off and revealing the paperyness of the sham, and there may also be seen papers to imitate different kinds of wood and which I regret to say may even be bought in the market to-day. Surely in this age of pretty wall papers and artistic designs such poverty of invention, to say nothing of the deceit, is indefensible. It is not so long ago since it was a common thing to break up a blank wall by putting in sham windows and painting on the sashbars and glass, and I have even seen fancy blinds painted on. And such was the rage forty or fifty years ago for uniformity, that if a house required a wing on one side, a similar wing had to be put up on the other, even although it was only a thin sham wall with nothing behind it. Some of you may have seen imitation colored glass made of paper which was intended to be pasted on to the ordinary glass of a window to make people think it was stained glass. These may be thought trivial details, but I hold no details to be trivial, and although we may not bow down to falsehood in that form, it is so hydra headed that other heads of deceit will arise in other forms to gain approbation.

Truth demands that in all design the nature and character of the materials to be used should be considered, so that the inherent quality of each should be brought out in the design. Let what we have be simple or expensive, but let it be at least what it pretends to be, and if at the same time it is good in design, then we can safely take pleasure in it with a good conscience. Nothing is too trivial for truth to hold sway. It should permeate down to the smallest detail. A great writer has put this admirably, yet not too strongly. He says: "Nobody wants ornaments in this world, but everybody wants integrity. All the fair devices that ever were fancied are not worth a lie; leave your walls as bare as a planed board, or build them of baked mud and chopped straw if need be, but do not roughcast them with falsehood." Very subtle forms of falsehood are creeping in under the guise of artistic effect. In the States especially you will see new houses built to look old, with the stones purposely chipped and broken and made to look weather-beaten, so as to give to a new house the effect which has only been put daintily and lovingly on by the finger of Time on an old one, after perhaps a century or two of caressing. It has affected modern draughtsmanship also, for new houses and buildings are delineated as if they were ruins crumbling into decay, and fictitious aids are freely sought after to enhance effect.

If honesty and truth could but pervade the execution as well as the design of our architectural and engineering works how many accidents and lives might have been spared. Every week, I would almost say every day, accidents happen from dishonest and faulty workmanship—vessels lost at sea, trains wrecked, bridges giving way, houses falling. But this faulty work is not confined to modern times; recently, the ancient central tower of Peterborough Cathedral showed signs of failure, and it was found necessary to take it down and rebuild it. In the process of demolition it was found to the amazement of everyone that the piers supporting the towers were only composed of a skin of good masonry and that the inside was filled in with rubbish. Surely the jerry builder has been an institution in all ages! Examples could be multiplied indefinitely, but enough has been said to make my meaning clear, I think. Entire honesty and thoroughness in everything is what is wanted, not only in what will be seen but also in what may not be seen. It is an old saying, "The Gods see everywhere."

I would close by quoting a sentence from an address delivered by Gounod at the Academie des Beaux Arts in Paris a few years ago. He says: "Art reposes in Truth. Wherever Truth is ignored and violated there begins or is accomplished the work of disintegration or death. Serve Truth. Truth alone gives stability and liberty. Serve her generously, valiantly, nobly. Yield yourselves to her. She is so divinely grateful that she will pay you a hundredfold the battles fought for her."

THE R. C. A.

AT a meeting of the council of the Royal Canadian Academy recently held in Toronto, the following committee was appointed to select pictures from the exhibition to be held in Montreal in February, and if deemed advisable to select works of art by Canadian arists generally, to send to the Canadian fine art exhibition at the World's Columbian Exposition, Chicago, which will be opened May 1st, 1893, viz. :—Mr. Robert Harris and Wm. Brymner, Montreal, and Mr. Homer Watson, Doon. Mr. Robert Harris was chosen to hang the pictures selected. Resolutions of sympathy were passed to the widows of the lately deceased members, W. G. Storm, architect, and Paul Peel, the artist.

It is the intention of the academy to make as good an exhibit of Canadian art at Chicago, as can be got together. The Dominion government has agreed to pay the expenses of the exhibition.

TORONTO ARTS STUDENTS' LEAGUE.

A very successful exhibition of recent work of the members was given from the 5th to the 10th inst., in the League rooms, Imperial Bank building. The exhibit spoke volumes for the industry of the members and likewise displayed a marked improvement in skill. A further reference to this exhibition and to the work of the League will appear in our New Year number.

ODDS AND ENDS.

In erecting office buildings and other similar large structures the most difficult problem in general is that of adequate light, without considerable sacrifice of space. By using here and there thick pieces of glass, set in light iron frames, for floors, some of the difficulty is removed, but there are always some rooms that depend upon reflected light. The office room in which this item is written has large windows, but blank walls only a few feet from them so that very little light comes into the room direct from the sky. It was originally intended to cover the walls referred to with white glazed tiles, but this was not done because of the high cost. It does not seem to have struck the architect or owner that almost the same result might be obtained by giving the walls a liberal coat of whitewash about once a year. The expense would be comparatively small, while the reflection of light from the white surface almost equal to that obtained from glazed tiles. Another means for reflecting light in dark rooms that is extensively used in office buildings in England is the mirror reflector. This consists of a mirror plate, finely corrugated on the surface and set in a strong wooden frame. It is hung on the outside of the window, the top being inclined at a proper angle to throw light into the room. As a rule the reflector is supported at the bottom on pivots, held in place by means of iron brackets secured to the window frame, while the top is supported by iron chains. The surface of the plate being corrugated, the light thrown into the room is well diffused. The writer has seen cases repeatedly where rooms in which it was necessary to burn gas all day were rendered light enough for all office purposes by means of these reflectors placed at each window, the reflectors being assisted by the walls and ceilings of the room, which were papered with very light satin wall paper.

* * *

To properly specify for the finish of hard-wood floors sometimes puzzles architects. The writer has seen several coats of raw linseed oil called for, when to use such would produce very unsatisfactory surfaces. One of the best ways to finish floors of this kind is to first give a coat of hot linseed oil, liberally mixed with dryer, then rub in paste filler and clean off in the usual way, taking care to leave the surface free from excess filler as far as possible. Now apply a coat of light shellac, sandpaper lightly all over, and putty up the holes and defects with a putty carefully colored to match the wood; then apply two or even three more coats of shellac and lightly sand paper between each, and finish by rubbing to a dull polish with crude oil and powdered pumice stone. An oak floor finished in this way will last longer than a finish by any other method, and very much longer than when finished with wax. Some painters would be inclined to omit the hot oil before applying the paste filler, but it pays well to use it, as it forms an excellent foundation and gives a durability to the floor as a whole.

* * *

Canada is fortunate in having upon its statute books a law regulating the sale of white lead which practically insures that pure lead shall be used when specified. The fact should not be lost sight of, however, that something more than purity is required in white lead; whiteness and fineness are very important qualities, and it is well known that there is almost as much difference between the various brands of pure lead as there is between chalk and cheese. The color of white lead may readily be tested by placing different samples side by side, when the whitest sample will be readily distinguished. It is not a bad plan to have a sample of zinc also; the zinc being a much purer white than even the whitest white lead ordinarily sold, gives a sort of standard and indicates at a glance how yellow the commercial white lead is. To test the fineness of white lead is not a difficult matter: Thin it with turpentine and spread on glass, brushing out as smoothly as possible, using a separate sheet of glass for each sample, and taking care to thin equally. This can be done by weighing the sample of lead and measuring the quantity of turpentine used in each case. When the glass is painted and is quite dry a comparison between the samples will show the relative fineness at a glance, while if the finger be drawn across the surface, the difference in fineness will be further perceptible. This glass test will tell something about the whiteness also.

There are few things more annoying in connection with store fronts than the condensation of moisture on the glass that so frequently takes place. Not only does the water run down and spoil the goods placed in the window, but it obscures the view and renders the window to all intents and purposes useless. There have been various means for curing the trouble patented, but none of them has met with very great success. No store front should be built without an open grating at the top to permit of a free ventilation, when this is provided there will not, as a rule, be much accumulated moisture. In case of existing store fronts where it is desired to provide means for ventilation, a piece of glass should be cut away and a revolving brass ventilator inserted, or a strip of glass may be cut away from the top of the window and two or three strips of glass held at the ends in a metal frame and arranged to lap may be inserted so as to form a glass shutter that can be open or shut at will.

ESCAPE FROM BUILDINGS IN CASE OF FIRE.*

By Chas. Baillairge.

Having been invited by your Secretary, Mr. Hutchison, to read a paper on some subject connected with the profession, I do not think I can hit on one more utilitarian and really important than that of "Evasion in Case of Fire."

For the last 30 or 40 years we have been endeavoring to erect "fire proof" structures, and great strides have been made towards the solution of the problem. Repeatedly has it been asserted that such and such a building was or might be considered absolutely fire-proof; and as often has each and everyone of them come to grief, generally with much loss of life, whenever taken in hand by the devouring element. As recently as last year did I see a list of some 28 theatres and places of amusement destroyed by fire in different parts of the world in a single month; and one can hardly, on any day of the year, take up a newspaper without the recital of some frightful accident, some holocaust due to the destruction by fire of a manufactory, a college or a convent, theatre, hotel, asylum and the like.

The motto used to be, "All brick and iron," or "Nothing but brick and iron," but that error has been exploded by the repeated failure of structures so built, where it is found that cast iron columns snap like glass when, after becoming heated by the combustion of the furniture and stores within the building, a jet of water from a fire engine happens to strike them; while wrought iron columns, joists and girders also fail, by warping and distortion; and it is now incontestibly admitted on all hands that cast and wrought iron columns, beams, girders, etc., can only be used and relied on to stand in case of fire where they are enclosed in brickwork, or thoroughly enveloped on every side with terra cotta or some other refractory substance of the kind; and hence the philosophy nowadays of erecting buildings composed of a skeleton frame work of wrought iron or steel encased in brick work—the iron affording the stability required while the brick work forms the protection against destruction by fire.

It may be considered practically impossible to render buildings of all kinds absolutely fire-proof, or to the extent of preventing at least their partial destruction. We cannot, for the sake of an eventuality which may never occur, render ourselves uncomfortable and miserable for a whole lifetime by resigning ourselves to tread on cold stone, cement, tile or other forms of incombustible flooring. We cannot make up our minds to the life-long handling of cold and heavy iron sashes, shutters, blinds and doors. Floors in our dwelling houses and our schools, and in the bedrooms of hotels, etc., must still for health and comfort continue to be made of wood. You cannot have your little ones trot around in their bare feet even on so cold a floor as oak, merely for the sake of its slow burning qualities. And, independently of the effort and fatigue of handling iron doors and casements, look at the cost of them as compared with wood—the first cost and and then the subsequent one of repairs; for buildings must in future settle and subside unequally, and what will cost you a cent to chip and shave a wooden sash or door to make it fit, would cost a dollar if it were iron; to say nothing of the fact that the iron sash, the folding casement more especially, could hardly be made so close a fit against the entrance of cold air, and, therefore, not so comfortable.

The treads of stairs, if not the carriages, must in dwelling and tenement houses and whenever carpets cannot be afforded, continue to be made of some such non-conducting soft wood as pine or hemlock, spruce or balsam, where you can use your bare feet without the danger of taking cold as when walking over oil cloth. Our tables, desks and chairs must continue to be made of wood, for who can submit to constantly touch or come in contact with metallic surfaces without untold annoyance, discomfort and ill humor. And so must our couches, our sideboards or buffets and our bedsteads be made of wood, were it only for the fact that a wooden bedstead can be bought for $2.00, while an iron one costs five times the amount. Nor would any adequate advantage be obtained in the use of iron chairs, if they could be made as cheap as wood; for, as no one could use such, so to say, freezing or heat abstracting seats, they must be suitably upholstered or cushioned. So would couches have to be if they also were of metal.

Now, since all buildings used for residential purposes, as dwelling and tenement houses, convents, schools and colleges, hotels and places of public resort and amusement must, therefore, have wooden floors, wooden

* Paper read at the Third Annual Convention of the Province of Quebec Association of Architects.

doors and sashes, wooden furniture, and, as in the case of hotels, etc., thickly upholstered furniture, curtains, portieres, carpets, mattings and the like, it follows that, even if in other respects fireproof, that is, if the building be indestructible by virtue of its iron joists and concrete floorings, its brick partition walls and iron roofing, still does it and must it contain a large amount of combustible and smoke producing material, and the gases more than enough when ascending from one single lower floor or story to stifle all the inmates of the floor above. The smoke and heated gases from below will immediately ascend through every stairway, through every elevator or sliding cupboard, through ventilating and hot air or hot water flues, or recesses in the walls. They will follow up along and through the holes made and left by plumbers around soil and sink pipes, electric and other wiring, and they must be counted on as surely as the fact that they cannot be excluded, eliminated or got rid of.

It follows that as no one can face such smoke and heated air or gases for more than a few seconds at a time, without the risk of choking, the way out of the burning building must be immediate. To have to grope through a long and maybe winding corridor to reach a fire escape at the end of it is inadmissible, impracticable. No one can stand the smoke for a sufficient length of time to do so. The fire escape must be at hand. It must be everywhere, with nothing more to do to reach it than to step over your window sill on to an adjoining balcony, or, in the case of a person occupying a front room in a hotel, cross the corridor into and through the rear room opposite and through the window thereof on to the said balcony leading to the fire escape stairway. There is no other possible certainty of escape than by the means I propose. Portable fire escapes may be and have been efficient in cases of private residences, or buildings where there are only half a dozen or a dozen people to be saved, the brigade having time to mount the ladder and make as many trips up and down as there are human beings to remove before the fire gets sufficient headway to render escape impossible by that means—but many impediments exist nowadays to the free use of the fireman's ladder, such as lines of wire and cables for telegraphing, telephoning, electric lighting, and electric transit, and oftentimes the ladder cannot reach the higher upper floors or stories.

Elevators cannot be relied on for evasion in case of fire, as, though the car and its surroundings be thoroughly fireproof and the fire or flames cannot travel through them from one floor to another, they act as chimney flues, the smoke and heated air rising through them to the exclusion of any possibility of escape in that direction. The iron stairways stipulated in the Boston and New York fire acts are no better than the elevators just alluded to, except that until invaded by smoke and hot air from a fire below, a larger number of inmates might pass out in much less time, than by the comparatively slower elevator process, due to the necessary intermittency of its trips up and down.

Fire escape ladders attached to outer walls are now to be found in very many instances, and it is unfortunate that we attach too much importance to their existence and seem to think that provided buildings have such ladders all is right and safe. Now, this is in most cases quite the contrary. Such ladders are no doubt of some use to able-bodied men and women, but of what use, let me ask you, gentlemen, is such a ladder to a child, to a young and delicate female, to an old man or woman, to an infirm person, even if it could be easily reached from any part of the building, which it never is and never can be, since, as before stated, no man, woman or child can before being stifled reach such a ladder through a long and winding corridor. Again, there are those who, though otherwise able to take care of themselves, become dizzy and helpless the moment they look down from any height, as from the upper floors of a building, and to whom the ladder would also prove useless. For a factory, no doubt, a ladder may answer, as the inmates are all able-bodied persons; but what about an asylum for the old and infirm, what about a convent, a college, with dormitories generally in the attic or upper floors, the other stories being used as class rooms, etc.; what is to be done in the case of a hotel with bedrooms in the upper flats and not extending below the third.

I think I may be allowed to say in my own name and in the name of the whole profession that nothing but a regular and commodious stairway can be considered safe under the circumstances, and this stairway must have no direct communication with any part of the building from which escape is to be had. This is imperative, and a *sine qua non* of the absolute safety of the proposed system: for, as already stated, if the stairway to be used as a fire escape does communicate with the building or apartments to be subserved, and if any one of these apartments be on fire, the ascending column of smoke and heated gases will effectually prevent escape in that direction. The communication must be indirect, that is, it must be from the building to an outer landing and from the latter to the stairway, thus preventing the possibility of the existence of any current through the shaft capable of drawing the smoke and heated air into it.

Now, the proprietor of the hotel, if it be one, will not (you may take your oath on it) for the sake of an eventuality which may never occur, deprive himself of a single foot of otherwise available space within the walls of the buildings; and if the stairs were built within the building, and taking up, as they would and must do, the space of an ordinary upper floor bedroom, that is one room on each flat or 5 to 6 rooms in the total height, the scheme would be objected to and no proprietor might be found to carry it out. And not only must no otherwise available space be devoted to the purpose or sacrificed as it would be said to be, to a doubtful eventuality; but neither would the manager of the establishment allow of any of his arrangements or requirements being sacrificed in the premises. None of the communications from one apartment to the other on the ground or any other of the floors of the edifice must be in any way impeded.

In the case of all buildings with interior courts for light and air the proposed fire escape stairway must, as shown on the accompanying sketches, be erected in the rear of the building, where it can be done inexpensively of 12" or even 8" brickwork, instead of towards the front where it would have to be made an architectural feature of the building and, therefore, ten times more costly than where proposed, as in such case the galleries would also have to be made architectural features of the design and so much more costly on that account. The stairway being in the rear, and as, to render escape effective and complete, the front or open must be reached, then must a corridor be made right through and through the building, and this corridor must be fireproof to be of any real use; and to be fireproof it must be like the stairs themselves, cut off from all possible communication with the remainder of the building, or in other words there must be no other door or opening into it or leading from it than the doorway from the foot of the stairs towards the rear and the door at the front or the outer end of it. This corridor should be situated at ground floor level, the level at which the inmates must escape into the adjoining street. But this would cut off communication between those portions of the building on either side of the corridor. No other solution, therefore, presents itself than that of elevating the corridor to a height sufficient to pass under it.

Now, we all know what a mezzanine is, or an *entre sol* as they call it in France. This mezzanine or dwarf story has a most important function to perform by being taken in or left out to suit. For instance, say the clear height of the first or main story of the building, whatever it may be, is 18 or even 17 feet. This may be divided into a 9 or 10 ft. and a 7 ft. story with an allowance of one foot or less in height for the floor between the two, and while the entrance hall or vestibule, stores, dining, meeting and other large and important rooms on said first floor would be made of the full height of the story, or 18 feet, other rooms for secondary purposes and of smaller dimensions would only be made say 10 ft. high with a 7 ft. mezzanine above them, to be devoted to servants' bedrooms and other domestic purposes with convenient stairs for access to them here and there. Through this mezzanine or *entre sol* would the fireproof corridors therefore pass, as shown in section, and thus the proposed system of fire escape becomes complete, certain and effective, without the possibility of giving rise to one single complaint on the part of the proprietor, tenant, occupant or manager of the establishment; for an inspection of the plan and section will show that from every story of the building above the 1st from which escape can be had direct into the street, flight will be simultaneous and, so to say, instantaneous, every occupant of a rear room stepping out direct over his low window sill into a narrow iron gallery (of open lattice work, not to interfere with the light below) communicating with the stairway, while each occupier of a front room has merely to cross the corridor and pass through the room opposite his own to get access to the gallery staircase. There can be no jamming of the occupants of one floor by those of another, for since the exit from the room is simultaneous on each flat the occupants thereof will be simultaneously or at the same time descending their respective flights of stairs.

It only remains to say that in the case of a church or place of worship, a music hall, a theatre or circus, with more than a single tier of boxes or galleries, the fire escape galleries or balconies must of course be towards the street or open, in which case they would be made ornamental features in the design, as in the new theatre at Antwerp in Flanders where to each of the tiers of boxes there is an outer gallery or a balcony continuous around the building and 25 exit doors to each story with stairs descending from the fifth tier to the fourth, from fourth to third and third to second, whence the last flight of stairs or that to reach ground level is temporarily suspended to preclude entrance to the buildings and released in case of fire by merely pressing the foot upon a spring.

Now, gentlemen, you will be naturally curious as to the cost, that is, the additional cost of carrying out the scheme, and to leave no room for doubt in the premises I annex an estimate thereof, founded on a closely detailed calculation of all the quantities, where on cubing the building at only 10 cents a foot we get say $160,000 for a hotel 200 feet by 100 feet and 100 feet in height or five stories, exclusive of basement and attics or mansard story (7 floors in all). The fire escape, including, as already set forth, iron galleries around each of the two inner courts, one to each story above the first or main floor, with two stairways, one to each court and corresponding fire proof corridors and stairs to street level, comes to $6,546 or very nearly 4 1/10 per cent. of cost of building. In the case of a similar building used for manufacturing purposes and composed of large apartments and where the furniture and upholstering being a minimum and the smoke from an incipient fire below much less in quantity and less intense, and therefore less hurry required in vacating the premises, the length of gallery to each floor might be reduced by half, which would reduce the additional cost of carrying out the system to something less than 3 per cent. of the cost of the structure.

ESTIMATED ADDITIONAL COST OF FIRE ESCAPE FOR ANY BUILDING CARRYING OUT THE SYSTEM.

Taking the building to be 200x100 ft. or 20,000 ft. area with deduction of two open courts of 40x50, we get net area of 16,000 ft., which into 160 ft. high, gives 1,600,000 ft. cube at 10cts—$160,000.00.

FIRE ESCAPE.

Girth of courts, 180 ft. x 2 = 360 ft. x tiers = 1800 ft. lin. iron balcony 2½ feet wide (see detailed estimate of ft. lin.) at $1.85	$3,330.00
Add cost of enclosure walls to stairs (see detailed est.) $800 x 2	1,600.00
Add cost iron stairs (see also detailed estimate) $315.00 x 2	630.00
Add cost of fire proof corridors through the building from rear to front (see detailed estimate on sheets of diagrams, $493.00 x 2	986.00
	$6,546.00

not quite 4 1 10 ₀ or cost of building.

LEGAL DECISIONS.

IN the case of Rosebrough v. Eastwood, recently tried in the Western Division Court, Toronto, the defendant, who was the owner of a house for the erection of which the plaintiff had been given the contract, was ordered to pay $43, the full contract price, for work which had been rejected by the architects and replaced by another contractor.

MCKITTRICK V. PERRY:—This was an appeal by the defendant from the judgment of Judge Morson, judge of the county of York, given in favour of the plaintiffs in an action brought in that court and tried befor the judge without a jury. The suit was entered to recover the price of a furnace sold to the defendant for the purpose of heating his dwelling; the defence being that the furnace did not heat the house, and there was also pressed a counter claim for damages by reason of the defective heating. Judgment was given by the junior county judge for the full amount claimed by the plaintiffs, with costs, and the counter-claim dismissed with costs. Appeal allowed; the plaintiff's action dismissed with costs; judgment entered in favour of the defendant for $50 damages and the plaintiffs permitted to remove the furnace.

A case of considerable interest to architects and builders was recently decided in the county court at Winnipeg. In October last Mr. C. H. Wheeler, architect, sued Mrs. Joseph Wolf for commission in connection with the construction of her residence on Kennedy street. His original claim was $241 and his suit was for a balance of $161. Mrs. Wolf counterclaimed for $1,000 damages on the ground that the stone foundation had not been built 18 inches above the sidewalk and $100 further on account of defective work in the cellar. Evidence was submitted that the foundation was actually higher than the specifications called for. A number of witnesses testified that any damage caused to the cellar arose from the non-completion of the sewer on Kennedy street and the impossibility of getting rid of the water rising from the ground. The contract also provided that the cellar should not be completed until the sewer connection was made. Another point raised by the defence was as to the amount of commission to which the architect was entitled, the defendant and her husband contending that he had agreed to do the entire work for 2½ per cent. Professional evidence was given that 5 per cent. was the usual commission and the plaintiff and his son gave evidence that the defendant agreed to pay that amount. The jury gave a verdict for the plaintiff on both items of the counterclaim and for the full amount sued upon, less $13.50. A large number of witnesses was called on the part of the plaintiff, including several builders and contractors, and the case lasted a portion of two days.

The case of Pendarves v. Monro, reported in the current number of the Law Reports, should be noted, though it does not lay down a new legal principle, but simply emphasizes and exemplifies one which has been for some time in existence. Article 41 of Roscoe's "Digest of the Law of Light" states that "when a right is claimed in respect of windows in a new building coincident, wholly or in part, with windows in an old building, the owner thereof must show clearly that the new windows are coincident with and contain the area of those which have acquired the right light." This principle was enunciated by, among other cases, that of Fowler v. Walker, and it is this principle which Pendarves v. Monro emphasizes. The identity of the old and new windows was not proved. "By reason of the omission," said Mr Justice North in his judgment, "to keep any plan, there is no evidence which satisfies me that any part of an old window can be identified with any part of an existing window." In the work from which an extract has been given, the author states in the note to article 41, that when a building is to be pulled down, a plan showing the position of ancient lights should be made and kept with the title deeds. The place in regard to which the dispute in this last case arose was in Sardinia-place, Lincoln's Innfields, and the old houses were pulled down in 1872: therefore, being buildings in the center of London, it was eminently disirable that plans should have been kept. The occupier of the building from 1869 to 1872 made an affidavit giving particulars of the old windows, and stating that he believed that the new windows "cover in whole or part the ancient lights." But, as we have seen, this was not enough,—the evidence was too vague. The practical result, therefore, is that without a plan it is almost impossible to establish a right to light in respect of windows in a new building which have not themselves acquired a right, but are alleged to have such a right in respect of old windows in a demolished building, with which they are alleged to be identical.—*The Builder.*

MANUFACTURES AND MATERIALS

BRICKMAKING AND BRICKBUILDING IN NOVA SCOTIA.

The extensive forests in this country, causing comparative cheapness of wood as a building material, has tended much to retard the general use of bricks in the construction of buildings, public as well as private. Outside of the capital city and a few of the larger towns, it is rare to find a brick dwelling; the few which may be seen are crude in appearance and entirely devoid of any ornamentation. The idea that a brick building can be made handsome in appearance, without the use of face or repress brick and stone trimmings, has yet to be developed.

Face brick commands a high price, and stone trimmings are expensive, and beyond the reach of the ordinary builder. A prejudice also exists against brick amongst many, on the ground that a building constructed of this material is liable to be damp. This is owing to the hitherto defective mode of building, no air space being left in the outer walls. However, of late years, this factor is recognized, and almost any one now understands that a brick building can be rendered more comfortable for winter or summer use than one built of wood. Again, there are in the rural districts of the province very few skilled masons and no regular bricklayers. What we have are fairly good all round men; they will build a rubble foundation, lay a brick wall, or lath and plaster in a plain, unpretentions manner. It is quite easy, on the other hand, to find a carpenter skilful enough to build you a wooden house in the very latest improved modern style, and just as easy to obtain the manufactured lumber from the many sawmills, planing and moulding mills and sash factories to be found in any ordinary sized town. The tourist from your country, who, anxious to escape the siroccos of your heated cities, and lured by the many press notices this year of our country, to spend their vacation with us, have seen in our rural districts many dwellings which attest the skill and æsthetic taste of the worker in wood and the excellence of the painter's art.

Brickmaking in this country is only in its infancy. You can count the brick-yards on your ten fingers, and yet the country is full of the material for making red brick of the finest description. With two or three exceptions the operation of brickmaking is conducted by hand. The clay is mixed in an old-style pug mill turned by a horse, the bricks are struck by hand, laid on the ground to dry,—it it rains to be washed away,—hence the common brick are roughly made, as a rule, and utterly incapable of making a finished wall. The exceptions, where steam is the motive power, and brick machines used to strike the brick, are in this county, with one other yard I understand in Pictou County started this summer.

The brick made by the International Brick & Tile Company, whose works are situated here, are moulded automatically in one of Creager's machines, driven by a forty horse-power engine. This company makes only common brick, but their brick have such smooth faces and square edges that they are being used for some purposes instead of face brick. The clay on the property of this company is of a superior quality, entirely free from grit, and is taken direct from the bank to the pug-mill. When moulded, the brick are dumped on pallet boards and placed in racks to dry, this being the only yard in the province in which the bricks are dried in this way. In all the yards the bricks are burned in the old style of kiln. Wood is now used as fuel, and at present it is kind of cheap, but the time will come when coal must take its place. There is not a "Eudaly," "Hoffman" or "Perfect" kiln in the country. Time and again I have urged the management of the company with which I have the honor to be connected to investigate the merits of the new and modern mode of burning, as compared with the old and, in my view, expensive, wasteful and antiquated methods, but without success. However, as everything comes to him who waits I yet hope to see a modern kiln as part of our plant. No ornamental brick is made in the country, and as for terra cotta it is unknown. Pressed brick is made in some of the yards, but they are manufactured by hand machines of antiquated construction. I should like much to see a Raymond or some other of the repress machines with which your manufacturers produce the beautifully moulded forms of brick and terra-cotta shown in the catalogues I have seen, and embellishing your fine and artistic brick edifices. Speed the day when ignorance and folly shall give place to the beautiful and edifying, as well as useful, in the construction of our residences and public buildings. Then may we hope to see brick predominating in our rural towns and settlements as the material of which to construct our dwellings, and such dwellings as shall combine art with utility, and which will not require constant repairs and the application of paint every now and then to keep up appearances.

To return, the Annapolis Valley, or "Evangeline's land," as it is now poetically known, contains vast deposits of argillaceous clay which becomes when burnt of different shades of red, from a bright toned terra-cotta to a deep cherry; just beside these deposits of clay are often found beds of sand sharp and fine, most of which can be used without screening. Moulding sand mixed with iron pyrites can also be obtained for experimenting in coloring, but usually with our clay it is not necessary. I have lately met with a description of kaolin which if properly treated, can be made into buff brick or terra cotta. It awaits only enterprise and capital to produce the manufactured article. We have the raw material, and the market will soon create itself. Our red clay, also, is suitable for drain tiles; being free from grit or stone, it can be easily worked through the tile machine. The market for this class of goods in a few years will be practically unlimited, as under-

Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 15th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1892.

PRESIDENT	S. G. CURRY, Toronto.
1ST VICE-PRESIDENT	KING ARNOLDI, Ottawa.
2ND VICE-PRESIDENT	F. J. RASTRICK, Hamilton
TREASURER	D. B. DICK, Toronto.

COUNCIL:

WM. G. STORM	Toronto.
DAVID EWART	Ottawa.
S. H. TOWNSEND	Toronto.
JOHN E. BELCHER	Peterborough.
EDMUND BURKE	Toronto.

REGISTRAR AND LIBRARIAN:
W. A. LANGTON - Canada Life Building, Toronto.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1892.

PRESIDENT	V. ROY, Montreal.
1ST VICE-PRESIDENT	J. NELSON, Montreal.
2ND VICE-PRESIDENT	H. STAVELEY, Quebec.
SECRETARY	A. C. HUTCHISON, Montreal.
TREASURER	J. Z. RESTHER, Montreal.

COUNCIL:

A. T. TAYLOR, F.R.I.B.A., R.C.A.	Montreal.
M. PERRAULT	Montreal.
A. F. DUNLOP, R.C.A.	Montreal.
J. J. BROWNE	Montreal.
J. HAYNES	Montreal.
D. OUELLET	Quebec.

TORONTO BUILDERS' EXCHANGE.

BOARD OF DIRECTORS:

WM. J. HILL, President.	WM. PARK.
GEO. MOIR, 1st Vice-President.	JAS. CRANG.
GEO. OAKLEY, 2nd Vice-President.	M. MURPHY.
DAVID WILLIAMS, Treasurer.	J. LISTER NICHOLS.
JOHN ALDRIDGE.	WM. PEARS.
BENJAMIN BRICK.	

JOHN L. PHILLIPS, Secretary.

VOL. VI.

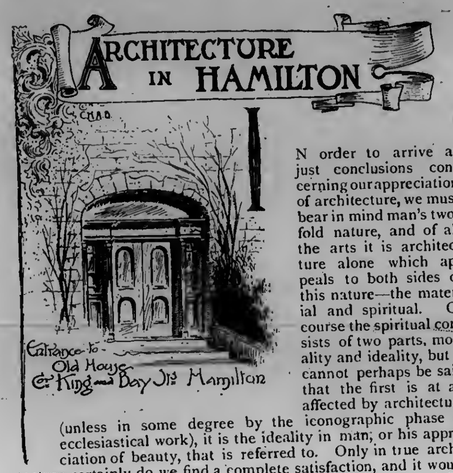
FIVE years ago the CANADIAN ARCHITECT AND BUILDER was launched on the journalistic sea as the representative of the architectural, engineering and building interests of this country. The present New Year Number is intended to mark its safe passage through the shoals which at the outset usually endanger and often wreck the lives of ventures of this character. A comparison of this with the initial number, will suffice to indicate the progress which has been made. While it is a matter of gratification that many of the crudities which marked the earlier numbers have disappeared, we are conscious that perfection is yet far distant, and the realization of this fact will prompt to constant endeavor in the direction of the ideal.

Our sincere thanks are extended to every person who has assisted us to achieve the present standard, and we hope for a continuance of their aid in the future. Especially would we acknowledge the assistance given us in the production of the present number. To Messrs. Darling, Sproatt and Pearson we are indebted for the design for front page of cover, to Mr. Henry Simpson for frontispiece, and to the authors of the special articles on numerous subjects appearing in this issue. Nor would we omit mention of the manufacturing and supply firms, whose enterprise and liberality are abundantly manifest, and who are deserving of reward at the hands of architects and builders, who are extensive users of the materials which they offer.

We trust that to all connected with the building interests 1893 may fulfil the present indications of a prosperous year.

THE address of the President of the R. I. B. A. at the opening session for 1892-3, covers four closely printed pages of *The Builder*, and deals with a variety of subjects, including Draughtsmanship, Architects' Education, Examinations, Qualification of Fellows, The Institute's Publications, Capital and Labor, The Chicago Exhibition, Preservation of Ancient Buildings, The Education of the Public Taste. It would be instructive to receive once a year from the Presidents of our Provincial Arcitectural Associations a similarly comprehensive review of questions relating to the architectural and building interests of this country.

IT is with pleasure that we call attention to the letter in another column of Mr. John L. Phillips, Secretary of the Toronto Builders' Exchange, advocating the formation of a Provincial or National Association of Builders founded on lines similar to the National Association of the United States. Our correspondent enumerates some of the reasons which should serve to call into existence such an organization. There are many others which might be mentioned. Canadian builders are far behind in the matter of organization their brethren in the United States and the Australian Colonies. They are also behind all other branches of trade and industry of equal importance. Lastly they are behind, very much behind, the labor organizations, one of which, representing the International Stonecutters' Union, has been deliberating in Toronto during the past few days. Why should not the employers meet in like manner and discuss questions affecting their interests? The success which has attended the organization of the Toronto Builders' Exchange should prove an encouragement for the extension of the idea in accordance with our correspondent's suggestions, in order that questions of general as well as local interest, including the important subject of legislation affecting the building trades, might receive proper consideration. We hope to see the subject thoroughly discussed and early action taken. The ARCHITECT AND BUILDER will willingly place its columns at the disposal of those who may desire to express their views on the subject, and will otherwise assist in every way possible the carrying out of the idea.



IN order to arrive at just conclusions concerning our appreciation of architecture, we must bear in mind man's twofold nature, and of all the arts it is architecture alone which appeals to both sides of this nature—the material and spiritual. Of course the spiritual consists of two parts, morality and ideality, but it cannot perhaps be said that the first is at all affected by architecture (unless in some degree by the iconographic phase of ecclesiastical work), it is the ideality in man, or his appreciation of beauty, that is referred to. Only in true architecture certainly do we find a complete satisfaction, and it would seem safe to judge architecture by the degree in which it satisfies or fails to satisfy these requirements of our nature.

As in daily life we have first to give our attention to material wants, so in architecture, and if these are fully met and we build in truth, our inner nature will also find some response. Beyond this, it is only a matter of how much and in what manner we decorate our construction. For a building to be truthful, it not only must be built of materials which honestly proclaim what they are and which are used in a logical manner, but it should also suggest its purpose, and the exterior express its interior arrangements.

This point can be well illustrated by reference to the new Bank of Hamilton; here the lighting of the large banking room is accomplished by two rows of windows disposed in such a way as to strongly suggest two internal stories. Of course it was done to carry out the motive which had been adopted, but it is not truthful and one of the first principles of architecture is violated. In other respects this building is rather successful; the general conception of it is good, the detail is refined, and the carving shows signs of life and is well designed. Unfortunately though, the building is in the wrong place. The site is one of the finest in the city, and should have held a building of more imposing character. For this reason adverse criticisms have been passed on it, which would have been uncalled for had the building been elsewhere.

The Bank of Montreal may be cited as the best type of public building in the city. Although there is nothing very striking in its conception, the effect of the whole is good; its purpose is well expressed, and the interior truthfully portrayed; the detail both of mouldings and ornament is refined and well studied and thoroughly in keeping with the style—a phase of Florentine Rennaisance. This is a point which is worth laying some stress upon. The building is in perfect harmony throughout—not, as is sometimes the case, with features of part being in one style, those elsewhere in another, then probably the mouldings in a third, and the carving a mixture of several styles not included in any of the rest. This is the way in which a great quantity of our modern work is designed. Not only this, but the detail is coarse and unstudied. The general aim seems to be to design detail in such a way that one can see every part of it almost half a mile away; this is of course a great mistake, sometimes amounting to positive vulgarity.

An example of coarse detail on a public building may be seen on the new post office. The old post office building, on the other hand, has some very nice detail and is quite successful in many respects—in fact, it is well worth studying.

The Canada Life Building is also a good example both of design and execution. It is carried out in brown stone, and is a very commendable piece of cut stone work.

St. Paul's Presbyterian Church is a building that Hamilton may well be proud of. It looks well from any point of view and is pleasing whether seen from a distance or closely inspected. It is built entirely of stone, including the high and graceful spire. This is the only stone spire in Ontario.

As far as domestic architecture is concerned, Hamilton has both good and bad. There is something quite charming about most of the old homesteads where the true feeling of a *home* is well expressed. They have an air of repose and refinement about them in striking contrast to much of the new work, which literally bristles with towers and turrets, calling loudly to every passerby to behold what wealth and power its owner must have. A tower is altogether out of place on a *home*; there is no reason for it but that of ostentation, and it certainly detracts from the essential idea of such a building.

There is a nice old house on the corner of King and Bay streets; although very simple it is quite pleasing with its colonial doorway, good detail and careful disposition of the openings.

Another interesting building is a quaint old place on John street, now used by Messrs. Gurney & Co. as a storehouse. The design, which has a strong Flemish feeling, is to be commended as being harmonious throughout; the proportion of the whole and its parts is satisfactory, and the motive is well followed. The exterior is hardly expressive of its present use, but when it was erected this of course was different.

Hamilton should have good architecture, for it is very picturesque, and gives the designer a better setting for his work than is usual in cities. Fortunately it has also a good architectural foundation, and it only remains for the future work to follow this up on progressive lines without violating the essential principles of good design.

C. H. ACTON BOND.

ILLUSTRATIONS.

BANK OF MONTREAL, HAMILTON, ONT.

This building was originally erected for the Bank of Commerce from the designs of Mr. Hay, architect, Toronto. It was afterwards purchased and has since been occupied by the Bank of Montreal. The street fronts are constructed of Ohio stone, and the remainder of Hamilton stone.

ST. MARY'S CATHEDRAL, HALIFAX, NOVA SCOTIA.

St. Mary's Cathedral is regarded as being the finest sacred building in Halifax. The architect was a Mr. McCarthy, of New York. The entire front and the spire is built of dressed granite. The sides are not in keeping with the front of the structure, but are built of ironstone with freestone facings. It is a matter of regret that a structure upon which so much money has been spent should be finished in this manner. If the whole building had been completed in a style to correspond with the front, and erected in a square by itself instead of allowing other buildings to hide a part, it would have shown to much better advantage.

BANK OF MONTREAL, MONTREAL.

The present main building was erected in 1846-47 from designs by Mr. John Wells, architect. It originally had a sloping roof and a dome. At a subsequent date the dome was removed, an attic story built and a flat roof put on. The beautiful piece of carving appearing on the facade was executed for the purpose in Italy. In 1885-86 extensive alterations were made from the designs and under the directions of Messrs. Taylor, Gordon & Bousfeld, architects. The banking room was enlarged to more than twice its original area, and entirely new fittings of marble and bronze put in; the whole interior was decorated with frescoes of subjects taken from the early history of Canada.

A new grand oak stair case was also added in front of the Savings Bank to give access to the head office. This facade was ornamented by bas reliefs in stone of subjects symbolical of Commerce, Navigation, Mechanics and Agriculture, executed by Holbrook & Mollington, carvers, Toronto.

METHODIST CHURCH, QUEBEC.

Of Quebec's twenty-five churches, only five are of Gothic design; of these, the one shewn in our view is the largest and in many respects the handsomest. It is built of grey lime-stone, from Deschambault, about forty miles from Quebec, on the C. P. R. line, fine hammer dressed, with tooled mouldings and some very good carving. Until within three or four years the apex of the east gable finished with a pinnacle similar to those yet remaining. Having become impaired by the action of the weather, the trustees, to save future expense, decided to remove it. This action, taken contrary to professional advice, has detracted from the appearance of the edifice. The church can seat comfortably a little over 1000 persons. A gallery extends around the whole interior, the part at the west end being occupied by the choir and organ. Immediately in front and somewhat below the level of this gallery is the platform and pulpit, while underneath the gallery is the vestry and other parlors.

Being built on sloping ground, a lofty basement entered from a street at the west end, is obtained, in which the Sunday School and various organizations in connection with the church find roomy, well lit accommodation.

The late Mr. Edward Staveley, architect, designed and superintended the erection of this church in the year 1848. Although 45 years have since rolled by, carrying away with them all the trustees of that time, as well as the architect, the mason, contractor and painter, and in all likelihood all the workmen who raised the building, the senior member of the firm who carried out the contract for carpenter and joiners' work still survives in the person of Mr. Simon Peters, who is as ready to-day as he was 45 years ago to take contracts of any amount.

The original cost of this church was about $40,000.

DESIGN FOR A TOWN COTTAGE TO COST FROM $1500 TO $2000.

"ELGIN BLOCK," YONGE STREET, TORONTO, ONT.,—DICK & WICKSON, ARCHITECTS.

CANADIAN ARCHITECT AND BUILDER COMPETITION FOR A CITY HOUSE—DESIGN BY "NEW YEAR" (MR. WALTER F. SIDDALL, TORONTO,) AWARDED FIRST POSITION.

NOTES BY A CANADIAN ARCHITECTURAL STUDENT IN LONDON.

THE benefits to be obtained from travel are so obvious to every one that it would be idle to elaborate what may be assumed to be a well established opinion. To study with what success architects have in the past succeeded in meeting the wants of their time under different conditions, and, it may be, with other materials—to note, too, their failures, and learn if possible how to avoid such in one's work—this must surely be as profitable a subject of study as any young architect could well betake himself to.

Coming from a country all whose institutions as well as buildings are comparatively new, to one where age lends dignity to its habits and customs no less than to its structures, one cannot help being deeply impressed, and perhaps somewhat awed. It is not always easy to discover whence the charm of many of these old buildings is derived. It would seem that Nature herself takes up an architect's work where he leaves it, and by a touch of color here and there, removes the harshness and crudeness of the original work, softens the hardness of outline, and in a hundred ways assimilates the building to its surroundings, till after the lapse of ages, it becomes impossible to tell whether the building or its surroundings conduce most to the charm of the view. At any rate one can hardly look with anything but reverence at the structures which have come down to us bearing the marks of many generations. There is, however, plenty on which to exercise one's critical faculties in the work being carried out in modern England. Here, at all events, an American feels himself on level ground, and is usually not slack to join issue with his English brethren of the T square. It is not my intention, however, in these notes to criticize or make comparisons of the work of English and American architects, but rather to note what has most interested me in the architectural world on this side of the Atlantic.

London would seem to be fast becoming the great centre of architectural and artistic work, as it undoubtedly is of literary work. Most American architectural students who cross the ocean for purposes of study seem to go to Paris. This would appear to be the general belief as regards the past, but more attention is now being given to English work, though it may not be quite safe to say that the tide has turned. Colonials probably have more sympathy with English work—certainly those from the antipodes have, if one may judge from the number of Australian students one meets in town.

Coming to London for the first time one is greatly impressed with its vastness, and this feeling is one that grows, for it is only after a year or two's residence that one begins really to appreciate what the simple word "London" means. It has, however, been spoilt in the making. How sadly disappointing is it to find a total absence of grandeur, composition or grouping. And this is the more annoying because after the great fire there was both the opportunity and the Man. It will be almost impossible now to give to it that unity as a whole which it might have had, had the authorities accepted and carried out Sir Christopher Wren's plan for its reconstruction.

Westminster Abbey is of course the building demanding first notice. Its interior is probably the most beautiful in England; fortunately it has not been scraped (an operation that gives to many English cathedrals an appearance of comparative newness), and consequently has all the effect of hoary age to help out the beautiful architectural detail. The manner of lighting from above is one of its great charms; the interior is always more or less shrouded in darkness, causing an effect of gloomy mysticism and grandeur. The unusually high nave roof of course greatly contributes to this, as well as the wonderfully artistic London atmosphere. The effect, to be understood, must be seen on some glorious summer's afternoon. The statues erected as memorials, in some instances seem to injure the architectural effect. Yet it may be that the Abbey itself derives an added grace by comparison with their hideousness. The north transept has been recently restored, and and seems to be a work of exceeding merit.

It would be impossible in this short note to do justice to all the old churches about town, but one cannot do less than mention the Tower, with its beautiful Norman Chapel; the Church of St. Saviour near London bridge, being restored under Sir Arthur Blomfield; St. Bartholomew, Smithfield, also under restoration by Mr. Aston Webb. This latter church is a perfect mine of Norman detail. Hidden away as it is near the great meat market, and completely shut out from view among slums, it is only recently that the majority in the architectural world knew of this jewel.

An exception to the criticism as to laying out streets and buildings for effect must be made to what may be called Parliament Square. The view of the Houses of Parliament and Westminster Abbey caught as you enter the square from the embankment or from Westminster Bridge, seen about sunset, is literally a dream in stone.

St. Paul's Cathedral, too, from whatever point it is viewed, is a building which by its great mass and powerful dome cannot fail to attract the most casual of sightseers. The durable Portland stone from which it is built has in places weathered to an astonishing whiteness, whilst other parts are almost black from soot; all of which tend to heighten its artistic effect. The dome poised aloft above all surrounding buildings, is seen from almost everywhere and becomes the centre of many a majestic view.

Old London is fast disappearing: there is still, however, much of the domestic work of the 17th and 18th centuries left standing, but it has to be sought for in out-of-the-way places. It is specially interesting from its relation to the colonial work of America, the slight difference in detail arising from the use of stone for out-door features in the English work, resulting in the mouldings being rather coarser. Time has lent them a dignity which their simplicity and directness of construction helps out, the whole forming a strong contrast to the fussy modern detail of work rising up around it. In and about the temple is to be found a curious network of courts and alleys containing many examples of this class of work Richly moulded and canopied doorways (mostly of brick moulded and cut to as exact an outline as if executed in stone); cornices of elaborate detail and considerable projection, sometimes in cut brick-work but oftenest in wood, meet one at every turn, whilst scraps of wrought-iron tempt the sketcher's pencil.

Mention must be made, however brief, of the mine of sketchable subjects to be found in the almost priceless collection in the British museum, not to mention south Kensington with its collections of art work of every description gathered from everywhere.

Whichever way one's individual tastes may turn, one cannot but be struck with the energy displayed by British architects of the day in adapting the architecture of the past to their present needs, and in solving what may perhaps be ultimately recognized as the beginning of a new style. The work of some of the leading men cannot be called either Classic or Gothic. Traditional architecture is nowhere the rule except among a few of the old school,—the leaders have made the plunge, and the youngsters gasp and flounder after as best they can. To an eye trained to American practice, most of the new work here seems lacking in strength and especially in breadth. Too much detail and too little constructive architecture seems to be the rule. The value of plain wall surface scarcely seems to be appreciated properly. The English architects seem to be very fearful of destroying the scale of a building by use of large openings and of large features generally, and rightly so to some extent, but it is carried to too great an extreme. Everything in its proper order, but seeing some of the buildings here makes one think that the designer has mistaken his calling, not architecture but furniture should have been his destination. So one would at least think, judging from the recent competitions and the mass of work seen in the streets. Fortunately there are some men who are the opposite of this, and whose work seems all the more pleasing by contrast.

Terra-cotta is greatly used, and no doubt largely responsible for the extreme richness of the work now being done, and perhaps the smallness of many of the buildings causes the architect, though frequently in vain, to give importance to his building by enriching it. The great number of windows required in this dark climate to light a building effectively have to be considered as affecting its simplicity, by cutting up the wall surface.

Terra-cotta and brick are used with surprising skill. Elaborate cornices, architraves of windows, sills and many other features, are not only executed in terra-cotta, but also in cut brickwork. Some of the terra cotta here is of a light pink, but most usually of a warm yellow tint, and has a slightly glazed surface. It does not always weather well, however, notwithstanding the boast of its permanence. It is frequently cut for ashlar work in rectangular blocks, and is not entirely free from having a hard machine look about it. The blocks being hollow have to be filled in with some material, and there is some danger when this is not very carefully done, of the terra-cotta splintering if heavily loaded.

Moulded and carved brickwork is executed with a specially made brick known as "rubbers" set in putty mortar, with a very fine joint. Mouldings are formed by rubbing them to the required section, the carving is then executed after the work has set; the whole is finished as sharp and true as if executed in stone. These bricks, though soft and not capable of standing great weights, seem to weather well. Examples are to be found nearly two hundred years old in London. One cannot but praise the quality of the masonry in the best buildings. Walls are thoroughly well bonded and built either with cement or in hydraulic lime mortar. It may be interesting to know that the Victoria tower of the Imperial Institute, some 260 feet high to top of masonry, while of stone on the face, is backed up with brick, built, of course, in cement. With the exception of Portland stone, there seems to be no stone used in London which is pleasing in effect when used in large masses; this, of course, adds greatly to the difficulties of the architect in getting a pleasing effect. The most effective buildings seem to be those where a combination of brick and stone is used as in New Scotland Yard.

Some of the carving seen on one or two recently erected buildings is good beyond all praise. This result is no doubt due to the fact that sculptors of the front rank have been secured, and have not thought it beneath their dignity to engage in this class of work.

In examining the details of modern English practice, one notices many peculiar features. Casement windows are very much used, and the greatest care is taken in jointing them so as to exclude the weather. Then again, there is a tendency to divide the heads of windows into small squares. Lead lights too are much used, glazed with clear glass. In the best work many of the joiners' mouldings are worked on the solid instead of being stuck. In brickwork the bond is always either English or Flemish; American bond is not even known. Fire-proof construction is common, and is usually of concrete filled in between girders, sometimes with a flat soffit, at others arched. Very light concrete is used, the aggregate being Portland cement and coke breeze. The ironwork seems to be very indifferent and is usually handed over to fireproofing firms who not only supply the material but also the drawings. There is little or no attempt on the part of the architect to plan the construction of the walls to meet the best special requirements of fire-proof construction, girders being often allowed to come over openings and rest on chimney breasts, or, indeed, very much wherever they happen to come. It is to be feared that this sort of thing happens in the work of even the foremost men as well as among the general rank and file.

In conclusion, it may not be amiss to point out that the advantages of two or even three years spent in London are of great value to the young architect who has already mastered the routine of office work. To be able to come in close contact with old work and study the development of the best modern work; to see different methods of construction, planning and preparing drawings; to be able to attend the architectural classes of the Royal Academy and the Architectural Association, and to test one's knowledge by subjecting oneself to examination by the Royal Institute of British Architects, are only small portions of a list that might be continued indefinitely.

THE ENTRANCE DOOR.*

It was suggested some time ago that a general effort by every member of our Guild should be made to give additional interest and profit to the winter meetings, and that this end would be helped on by some little preparation given subjects likely to elicit interested discussion. The subject mentioned by Mr. Langton is in pursuance of an idea that it would be of profit to, say, commencing with the doorway, proceed as it were to dissect a house, and from the old and the new, as we are able to recall them, discover faults to be avoided and excellencies to be revived or perpetuated. So as, no doubt, to leave the more vital parts of the house for a more competent analyst, I have been asked to enter the threshold by introducing for discussion "The Entrance Door." That pertaining to a dwelling house of moderate size is I think a subject large enough for one evening, and is one we are all most frequently interested in.

Considered as to its purposes, what are the requirements necessary to make the entrance answer all demands of utility and ornament?—for as to the latter all ages seem agreed in this, that whatever of art or adornment pertained to the house, it is on the doorways we find its concentrate expression, and the good sense of this wants no argument, as beauty wastes not its sweetness here unseen, and here bad ornament is a sin with aggravation.

The door of a dwelling house, its purpose in all cases being pretty much the same—to welcome the coming, speed the parting guest—why should they not, I venture to suggest, be all of a size? A good stout door, say 4 ft. × 7 ft., securely hinged, shutting truly into its rabbat, with solid lock and furniture, is an agreeable thing to handle, which very few double doors can be made. But, you say, how can wealth display itself by so meagre a portal? Yet, are there not examples of French, of Florentine and other Italian doorways, smaller than this, that by treatment of arch, jamb and lintel, and perhaps carved or mosaic spandril, are made infinitely more attractive than the double doors of America? The question I raise is, that except for buildings put to public uses, where it is necessary to give exit to throngs of people, is the insecure, unsubstantial looking, two-leaf door ever necessary or desirable? Should not the house that seeks to display some grandeur of proportions in its entrance, have space enough to give some hospitable shelter to the visitor at its doors and under recess, arched or otherwise, frame a door of our normal size by such studied devices of art as would render interesting the delay between the "knock and it is opened unto you"?

The size of landing of the front door is a matter of proportion, and although the nervous groping for the step caused by too small a landing is to be avoided, yet the landing can easily be made to look too large unless combined with other piazza. For elevation of door above the ground line I would make a golden mean about 3 ft. 6 in.—neither liking the necessities of the American high basement, nor being able to feel the charm of the English method, which likes to saunter into the house over one or two stone steps. Whatever the size of the entrance door, it should be deeply recessed, being different from a window, in which the reveal is more valuable inside. The door looks repellant which is near the outside of the wall, and for which no extraneous porch head or pediment will atone. The universal panel jamb of our colonial is a recognition of this, and is a feature that with the better understanding of a free, refined, classic detail now prevalent, might be revived, redeeming at least the terrace house from the commonplace.

As to the architectural treatment of the door opening, to give due prominence to this, the main feature of the house, all depends on the acquired knowledge of detail of the architect and his skill in adapting and applying to make suitable to modern requirements. Even around Toronto there are numbers of examples of the English combination of pillar or pilaster and entablature, fan and side lights worked out with considerable refinement. For instance, the drawings of the old Canada Company's entrance, recently shown in the CANADIAN ARCHITECT AND BUILDER, compares well with the similar specimens of Old Colonial the *American Architect* is so fond of reviving for instruction and reproof. So now that the bustling progress of the last twenty years (in which the doorways have had too little study of either architect or joiner) has had praise, it is likely we will all endeavor to do more studied work on this feature of the house. As to the most desirable position for the entrance to the house, although there are no doubt many fine houses with the doors in the centre of the front, it seems to me to commit one to a somewhat unvarying type of plan, where the hall is apt to be dark and only a means of getting to the rooms. Entrances on the corner or on the side, on the other hand, give the architect an opportunity to make of the hall a delightful loitering place, with enticing vistas into the rooms.

I seem to be about the end of my ideas on the entrance door, having got into the inner hall, forgetting that indispensable feature in our climate, the vestibule. This should be large enough to render progress between doors easy and natutal, but anything excessive in the size of vestibule is downright loss to the house, its purpose being merely analogous to a double window, for in any way to attempt to furnish the vestibule results in more convenience to the hall thief than to the occupants of the house.

*Paper read before the Toronto Architectural Guild, by Mr. John Gemmell.

ORGANIZATION OF CANADIAN BUILDERS.

TORONTO, Jan. 7, 1893.

Editor CANADIAN ARCHITECT and BUILDER.

SIR,—In accordance with the suggestion made by you some time ago, I beg to submit the following ideas that have occurred to me, with the earnest hope that a greater interest may be thereby incited among sister associations, which may result in the amalgamation of the various Builders' Associations throughout the country.

You are aware that the different exchanges and associations in the United States have united into a National Association, and that a convention is held every year in one of the leading cities for the purpose of discussing matters of interest to the trade, and of concerting measures to improve existing conditions. Through the courtesy of Mr. H. Sayward, of Boston, Secretary of the National Association, I am in possession of much valuable information regarding the progress of the Association. Among the results achieved thus far may be mentioned: 1st, the establishment of the "Uniform Contract"; 2nd, a fully defined method of apprenticeship; 3rd, a general plan for the joint settlement of disputes or differences between employers and workmen.

One very desirable result is being attained, in that workmen are becoming impressed with the fact that their employers are considering the questions that they have for so long a time been trying to solve; and they are thus becoming better disposed for a peaceful settlement of disputed points.

I may say that the Toronto Builders' Exchange is endeavoring to secure an amendment to the present Lien Law, which is acknowledged to be practically inoperate, so far as giving any security to the builder or supply merchant is concerned. Is it not reasonable to believe that such action would carry greater weight, and be more likely to succeed when proceeding from a Provincial or National Association?

I understand that the exchanges and associations in Australia and New Zealand have formed a Federal Association, with a very perfect organization, and judging from a report of their last annual conference, held in Brisbane last October, they have reason to congratulate themselves upon their success. It appears to me, that if our friends in the antipodes (who are separated from each other, in many cases, by long water stretches) can still meet, and hold such enthusiastic meetings, there surely is no reason why, in Ontario at least, where every facility for intercommunication exists, that a National or Provincial Association should not be at once formed.

I am sure that the Builders' Exchange of Toronto will heartily co-operate with other Associations to this end, and I think the assistance of the CANADIAN ARCHITECT AND BUILDER may safely be counted upon. I would suggest (with your permission) that the views of other Associations on this matter be expressed in your valuable journal. Allow me to state that any communications on this subject addressed to the undersigned would be received with much pleasure.

Yours truly,

JOHN L. PHILLIPS,
Sec'y Toronto Builders' Exchange.

SOME EXPERIENCES OF A STUDENT IN VENICE.

THE traveller abroad will save much time, trouble and money, if he will plan his tour and acquire information about it before starting. The experiences of a returned student of architecture ought for this reason to be interesting to those at home whose tour is yet before them. Though I was myself ill prepared for what I had to do, and my tour was, I am afraid, by no means a model always of the best thing done in the best manner, yet I think intending travellers of the same kind as myself may extract from a narrative of some of my experiences in Venice, which I visited first and where I stayed the longest, hints and information which may be not unuseful to them when they are preparing to go abroad.

While I was meditating my tour I gradually became aware that to mention my purpose to an old traveller was to be charged in reply with a list of practical hints about hotels, pensions, conveyances, etc. I found this rather dull conversation when my tour was more remote, but as it neared accomplishment, began to perceive its interest; and when, upon the eve of my departure from England, a sculptor recommended me to go to the Casa Kirsch in Venice, as a place frequented by artists and English, I made a careful note of it (as I would recommend the student to do with all such hints) and a few days afterwards found myself there.

On the first morning after my arrival as I was having my café, or first meal, in the Salle à Manger—not having yet learned to take it in my bedroom or in bed in the Continental manner—a young man, who had been transacting business there with a vendor of antiquities, apologized to me in the American tongue for interrupting my breakfast. We had a little conversation, for which I am still grateful to him. I was just then realizing my position of desolation in a strange land, and clung instinctively to a white man, particularly when I found that we had met before and that he was of my own profession. But it came out soon that he was on his wedding tour, and I perceived that he was cut off from me forever. He was, however, good enough to seek me out that evening to give me a piece of advice which I pass on as of the greatest value. It seems that the English and American schools of art furnish their students with medals or tickets of some kind, which, by the liberality of the Italian Government, are convertible into tickets of admission to public museums and galleries of art throughout Italy. A certificate from one of our provincial associations of architects would no doubt be enough to effect this for Canadian students now. I had nothing to recommend me, but my friend came to advise me to apply to the British Consul for recommendation, as a student, to these privileges. This I subsequently did, and found it of the greatest service to me throughout my tour. It is not only picture galleries and museums proper that are thus opened to the student, but all the ancient buildings, such as the Ducal Palace at Venice, the Monastery of San Marco at Florence, and others, which are preserved as monuments of antiquity, and kept in charge by the Government. If one visited them as a sight-seer only, once for all, the charge of a franc which is usually made for admission would not be so great a consideration, but a student needs to make many visits. If one puts himself in charge of Ruskin, who so frequently explains one object of study by reference to another, it is desirable to feel free to step for a few minutes only into the building which contains the object referred to. I think also that there are restrictions as to sketching, to which persons other than the holders of these government "promessi" are subject.

My American friend had only time to give me this information when his wife appeared on the scene and carried him off to get what she called "our sunset"—as if the world belonged to them. He was in the act of warning me that a solitary tour would be very lonely work, when he was snatched from me. I watched them going off in their gondola, into the sunset, seated side by side in happy companionship and conversation, and the night of solitude settled down upon me. With the taste of English still in my mouth, I felt the full force of the Englishman's sneer at the Continent as being inhabited entirely by foreigners. Here I was in the midst of them with nothing to meet the emergency but a certain amount of French vocabulary without any power of putting it together. This brings me to my third point, which is the importance of knowing French, or French and Italian, but French by preference, for it is of great use in Italy, whereas Italian is of no use in France. I was driven to speak in French after a time, for the supply of English guests at the Casa Kirsch soon failed, and for the remainder of my two months' stay in Venice I lived with foreigners of the most remote kind—a Pole and a Greek, who spoke all the languages of Europe except English. For a time there was a German also, with a scar across his face. During his stay the conversation was carried on sometimes in German, sometimes in French; or when a frequent visitor, a young Italian official with a long rat tailed cigar and a habit of gurgling airs from the opera in his throat, was present, the language veered to Italian. But I alone was able to speak English. When the German left us the conversation settled down to French. The Pole—a noble old man—was a poet not without fame (I have seen mention of him in an English review), and a beautiful talker. The Greek, a "philolog," was engaged in editing a text of Aristophanes from a manuscript in the library of Saint Mark. They had great conversations, from which I was excluded until I began to get the ring of it. I succeeded first with the Greek, who was very like a smart young American. He managed not only to make me understand him after a time but, what was more to the credit of his intelligence, seemed to understand me. The Pole found more difficulty. I am afraid, now that I come to think of it, that I can hardly have been an addition to the pleasure of conversation. I remember one day addressing a remark to the old gentleman which left him still visibly in the dark. Something called him from the room at that moment. I asked the Greek if he thought I had been understood. He replied, "When one is learning a language there are days when everything goes marvellously; words seem to come of their own accord; other days nothing goes, and one cannot make one's self understood. To-day is one of those days."

I had prepared myself rather hastily for the opportunities of Venice, and found myself not well prepared. I had read the shortened form of "The Stones of Venice," from which I had carried away the erroneous idea that Venice was builded of many coloured marbles. I had also read Howell's incomparable "Venetian Life," and was somewhat prepared to find Venice, after all, a city composed chiefly of dry land; but I was ignorant not only of the history of Italy but, in any proper way, of the history of architecture. I was puzzled to know where to begin my studies. It is all very well for Street, in his "Brick and Marble Architecture in Italy"—a subsequent acquaintance, I am sorry to say, he would have been invaluable as a travelling companion—to regard the monuments of the architectural centuries as a tailor on his travels might the foreign fashions. Street did work of the same kind; he even built vaulted churches. I do not say but that it was a pity that he should have devoted himself so much more to the practices of style than to the principles of beauty. At any rate his method of procedure was not that which would have occurred to me, I think, even if I had been more learned in the history of architecture. I had in my mind continually the very different conditions of Canadian architecture, and sought rather to study the reasons of the ancient designers than their results alone. With the idea of systematizing my attack on buildings by dividing all buildings into the same parts, and so viewing them in an orderly manner, to which conclusion I was driven by the *embarras de richesse* in which I found myself, I went to the library of S. Mark in the Ducal Palace to study in the first volume of the Stones of Venice, Ruskin's admirable analysis of buildings into their parts. When one has begun that wonderful book, it is impossible to leave its study incomplete.

In S. Mark's library no fire was allowed, and it was bitterly cold. The Greek, who spent about six hours a day there, complained of it too. But these southern continentals can stand far more in the way of cold than we soft dwellers in a more inhospitable clime. I have seen Italians sit for hours on a marble step in the icy shade which in a short time chilled me to the bone. Fire not being allowed in the library, much less was light, so that all study carried on there had to be done in the precious daylight. It was, therefore, a great comfort and advantage to me when the distinguished young Italian engineer who was superintending the restorations of the Ducal Palace, who both speaks and writes English and had himself a venerated copy of the Stones of Venice in his office, discovered me reading in the library and offered to introduce me to a better place. This was the library Querini Stampalia on the Campo Santa Maria Formosa which is warmed with delightful warmth and open until eleven at night. There is not only an excellent library, but the leading papers and journals of Europe lie on the tables, so that one can resume connection with the world if he cares to. I do not know whether the certificate of studentship I received from the consul would have obtained for me admission to this library without further reference. No doubt a student could procure from the consul what introduction is necessary. As far as I recollect, I came and went after my introduction without further question or scrutiny from anyone.

My troubles were at an end as far as study was concerned. With Ruskin as a guide and an opportunity of studying him so comfortably, I was not only happy, but I think profitably employed. Reading in the evening and making notes for study in the daytime, I circumnavigated the Stones of Venice in the course of my stay, verifying every principal allusion in the text to Venetian architecture.

Though founding my operations upon the Stones of Venice, I, of course, went outside of its limits also as objects came in my way. It was too cold usually for long sketching. A Canadian thinks of Italy as a mild southern place, but when such unwinterlike work as sitting out of doors to sketch is in question, though the thermometer does not feel the cold much, the draughtsman does. In a sheltered position in the sun it was warm enough—indeed on fine days delightful. But it is seldom that one gets a chance of sketching in the sun. Streets are narrow in Italy and get but little sun in the course of the day, for it is shade that is the principal requisite there. Courtyards and cloisters are little better, and the churches are veritable wells. The museums and galleries in which one sometimes finds material for sketching, and which in any case contain matter for the study of every art student, have at the most a brazier here and there, where one can warm one's fingers now and then, and which I suppose must reduce the chill of the air somewhat. But there was nothing of the sort at Venice. The old women who haunt the churches are usually supplied with a *scaldino*—a crockery pot with a handle like a basket, which contains charcoal with coals placed on the top, so that the fire eats slowly through the charcoal, giving warmth for hours. With one of these under her apron at her prayers, or still more effectually disposed for warmth when she stands up, the old women manage to carry out their religious exercises without dying from exposure to cold. Later on in my career in Italy I met a young English architect who wore an Italian cloak and carried a *scaldino* under it. I think there are many occasions when such an arrangement would be feasible and conducive to more careful sketching than I felt inclined to do, with the cold gradually creeping up my extremities and penetrating my vitals. I sometimes did careful sketching under these circumstances, but not as a rule. I always felt a little doubtful of the usefulness of spending much time in drawings for the sake of rendering them well. A drawing should have no more work on it than is required for the subsequent information of the draughtsman. How much work will meet this demand is a point which the object studied ought to decide. I always felt that I was employing my time best when I made my drawings rough, with the essential points only delineated, and notes and comments written on the edges. I carried a pocket sketch book—long and limber and about four inches wide—which was always ready for notes, and in the course of a morning's walk would fill several pages. Many things which one would otherwise sketch are done to perfection in the Stones of Venice (of which I had a large copy at home). Often also a suitable photograph takes the place of an elaborate sketch, leaving only notes to be made. Indeed, at Venice and elsewhere I adopted the plan of calling at the best photographer's early in my visit and inspecting his stock as a sort of illustrated companion to the guide book, that I might judge better of what was before me and what his photographs could do for me. At intervals, I looked in again after the day's work and selected photographs of what I had studied.

One soon acquires facility in grasping the points of a building, guided by the family resemblance that runs through the styles, and I am inclined to think that the practice of making note drawings rather than picturesque ones, is conducive to this facility.

Field glasses are a great addition to one's enjoyment and often of service, and a portable sketching stool also. I always carried both with me. One cannot work well standing, and chance seats besides being damp or cold, are usually round the corner. If I had thought of the need earlier, I should have brought a stool from England which would fold up in the form of a stick. I have no doubt they are fearfully uncomfortable, but so much easier to carry than my camp stool, which, when I come to think of it, was not a seat of luxury either. I did not always take it with me, as I might have done a walking cane stool, which would not have been out of place even on a ramble of exploration, but it always came with me when I went to study a definite object—even into picture galleries, where the fixed seats are not necessarily in the best position for attentive study of the picture. Light marching order consisted of the pocket sketch book and field glasses, and, of course, a rule and tape. Heavy marching order added the stool and a leather bag, containing a small board, sheets of paper and other materials and instruments. I could not always tell what I should use, and sometimes used everything, including the field glasses for remote details. I remember making a drawing through the field glasses, which took me two afternoons. I had a bad time with the boys on that occasion. They are always a great nuisance, and grown up people also. One has only to sit down to sketch to have a crowd around him in a moment. One would think that in Italy they are inured to seeing people sketch, but they are still more inured to loafing. On this occasion I was so unfortunate as to have selected an object over the very entrance of a school. The boys came out in floods, at what seemed to me very irregular and unreasonable hours, and surrounded me closely, several deep, and with calls in their heads to a man. It was a little warmer with so much animal life round me, and I needed it on one of these days. I had dropped my hat down the steps of St. Mark's, which lead to the crypt under the chancel. When I went to get it I found it in water. (Poor St. Mark, he is down in that moist sepulchre.) As the hat in its wet state was colder than none, I took it off. My sympathy, under the circumstances, was with the boys, for the spectacle of a man seated on a stool in the middle of the way, with opera glasses continuously elevated, notwithstanding that he was drawing, and with no hat, a red nose and a drop at the end of it, was a sight that to any intelligent boy's mind would require immediate investigation.

These are some of the toils of sketching, but there is still much to be done at night in turning shorthand sketches into drawings; finishing up and putting in order for future use; in reading books that will throw light on the present field of work or on one to come; and in writing the diary which is such a burden abroad and such a priceless possession at home.

Under these circumstances, it is questionable whether, with all its discomforts, solitude is not a state of advantage. I had a friend in Venice, an Austrian whom I had met in New York. I had his address and went to call early in my stay, but found him out of town. Subsequent visits at intervals always brought from his housekeeper the same answer, unintelligible except for words which I knew to signify "other town." Finally, just before my departure, I thought I would have a last shot at him, and found him arrived. He took me out in his *sandalo*—the Venetian equivalent to a dog-cart. Venice suddenly became a new place. Titled persons of different countries were pointed out to me, some of whom I had observed before, but they had not appealed to my unprejudiced mind as noble. We took off our hats to two young ladies whose name my companion murmured to me as we approached. I had had a good deal to do with an ancestor of their's in my meditations among the tombs. He was a Doge of the fifteenth century. It seemed preposterous to find two such pretty young ladies still above ground, and alluded to in simple fashion as "the M——'s". I hardly know why, but this more than anything seemed to shake the foundations of my life. Afterwards, when I found myself meeting English and American artists at dinner and talking English talk at the English Club it all seemed a matter of course, but I was glad I had had my fling in solitude with Ruskin.

HAMILTON CORRESPONDENCE.

HAMILTON, Jan. 5th, 1893.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—As you do not care to continue this discussion in your editorial pages, kindly insert the enclosed statement in your advertising columns and charge me at ordinary rates. I send this as there are proofs to back my previous statements which should be made known.

I am, yours faithfully,

C. H. ACTON BOND.

[In view of the course which one of the parties to the above controversy, whose name, however, has hitherto not appeared, has seen fit to pursue, we feel called upon in our own defence to make an explanation which will place the position of affairs in its proper light before our readers. The first letter, published under the *nom de plume* of "Doric," in reply to Mr. Bond's criticism, and which purported to have been written by some friend of the sculptor whose work had been called in question, was in reality sent to us with a request for its publication by the sculptor himself, Mr. Frederick Turner. A portion of this letter was of such a personal character that it was withheld from publication. Mr. Bond next reasserted the correctness of his statements over his own signature. Following this, on the opposite side of the controversy, came a letter from Mr. Watson, the City Building Inspector, which began with the following remarkable statement: "In reply to young (Mr.) Bond's communication of the 22nd of October last, *in reply to mine which you previously published*." Here it will be observed Mr. Watson distinctly claims to be the author of the letter signed "Doric," which, as above stated, was written by Mr. Turner. It rests with Mr. Watson to explain and the reader to judge what induced him to make a statement so directly contrary to the fact. Seeing that on one side the controversy was being unfairly conducted, we announced that it must close. A few days after the publication of this decision a letter reached us from Mr. Bond, in which he stated that he had proof of the correctness of his statements, and as his veracity had been challenged he thought we should allow him the privilege of substantiating his position. While recognizing the force of this appeal, we replied that we felt bound to stand by our decision, publicly announced, not to allow the controversy to proceed further, and the only way in which further publication could be secured would be by advertisement, to be paid for at the usual rates. After having informed Mr. Bond to the above effect, we received a personal letter from Mr. Turner, in which he charged Mr. Bond with having used his position as a correspondent of this journal to vent his spite and injure his (Mr. Turner's) reputation as a sculptor. He also forwarded to us a tracing from Mr. Bond's drawing, lettered "Motive for carving, to be executed in bold relief," the ridiculing of which he claims induced Mr. Bond to make a "spiteful" attack upon his work. In this letter he said, "it will be only fair to your old subscriber and advertiser that the impartial criticism (of the sketch) he (Mr. Bond) asks for should be given by you, showing as it must the animus that prompted his attack on myself." We replied that we must decline to be in any way personally drawn into the controversy, that being in a position to judge impartially, and from personal conversations with Mr. Bond on the subject, we had reason to believe that his criticism was not prompted by personal feeling, and that regarding the value and appropriateness of the suggestion contained in Mr. Bond's sketch for the carver, an architect who is a member of the R. I. B. A., on examination of the tracing said, that presuming the sculptor to be familiar with the various orders of architecture, he considered the sketch sufficient by way of suggestion. This letter was written in the most friendly spirit with the hope of inducing Mr. Turner to rightly view the situation. We regret that this desirable end was not achieved, as the following brief epistle, received a day or two later, will show: "Dear Sir,—Be good enough to discontinue my subscription to the ARCHITECT AND BUILDER and also my advertisement in your paper at expiration of contract." We are always glad to be of service to our subscribers and advertisers, but not in the direction which Mr. Turner seems to desire.—EDITOR C. A. & B.]

Halifax expended last year over half a million dollars on new buildings. About 125 dwellings have been erected at an average cost of $3,000 each.

The total value of the buildings for which permits were taken out in the city of Toronto in 1892 was $3,021,755, of which $1,200,000 was for the new city buildings; $1,166,000 for brick dwellings; $326,000 for stores; $257,000 for factories and warehouses, and the remainder for churches, schools and miscellaneous buildings.

The Brick Manufacturers' Section of the Toronto Builders' Exchange, at their annual meeting elected the following officers: J. Pears, president; W. Best, vice president; J. Price, treasurer; J. L. Phillips, secretary; representative on general board of directors, W. Pears; executive committee, W. Booth, H. Phillips and R. Simpson; auditors, A. Fox and F. Wakefield.

"CANADIAN ARCHITECT AND BUILDER" COMPETITION FOR A CITY HOUSE.

Editor CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—In compliance with your request we have examined the competition plans for "a city house," and herewith present our report.

We have given first place to the one under the *nom de plume* of "New Year," and the second place to "Etudiant." We beg to say in connection with this decision that the author of the first prize design would do well to give more attention to the rendering of his drawings. We regret having to criticize rather severely the top story of the second prize design, it being very inferior to the rest of the work. It is very bad judgment to break back the wall of the entire story for the purpose of getting up the two paltry gables; the roof construction is also bad; the planning is very good; the rendering is well done and would reproduce easily; the pier at the east side of drawing room bay is too light.

Several of the competitors, viz.: "Utile Dulci," and 'Palmer Perniex," violated the requirements of the competition by making buildings with two stories and an attic instead of *three clear stories*.

In the design submitted by "Chauer" the plan of the entrance has been sacrificed to the exterior. The drawing room lacks shape, being too symmetrical and formal to have good effect; the light well at west side would be absolutely useless, being barely two feet wide, and with the wall of another building built on the line the lavatories, back stairs and bath room, would be practically dark. A billiard room only 11'0" wide would be useless. The design is much too expensive for the appropriation. The drawings were not on the right sized paper. The draughtsmanship is quite clever and the drawings are very ship-shape.

"Utile Dulci" has sent in a well drawn set of plans and very well designed elevations, though not complying with the conditions. The plan is somewhat defective. Neither the reception room nor parlor is large enough to make a good room. Two main entrances to the one hall are not good; the mere fact of having one at the side does not make it in any way beneficial. A guest coming in one door and being let out the other would be liable to considerable confusion. Nothing is gained by cutting off the corners of the dining room. The kitchen door is too directly opposite the door to main hall. The back staircase and the first floor passage are dark.

The plan submitted by "Palmer Perniex" is good, though both staircases would be very dark. The esat elevation would be quite effective, but does not conform to the conditions.

The general lay-out of the house designed by "Incog" is rather good, but most of the rooms are much too small for a house of that character, the kitchen and bath room particularly so. The connection between kitchen and dining room is too direct and the doors too close together. Nothing has been gained and much lost by receding the pantry wall to give a north light to the dining room. The simple style of the elevations might be made to look very well, but to carry it out properly more study would be required.

There is one set sent in without a motto by a painstaking competitor, but the amount of work spent on his drawings could be much more judiciously applied. We would suggest that the author of it should study some good examples of rendering, and he would also do well to devote considerable time to practising printing, it being of great advantage to be able to print well and rapidly.

Yours very truly,

FRANK DARLING,
JOHN GEMMELL,
A. FRANK WICKSON.

[The names of the successful competitors are: "New Year," Mr. Walter F. Siddall, student with Messrs. Siddall & Baker, Toronto; "Etudiant," Mr. J. Eugene Payette, 3 Quesnel St., Montreal.—EDITOR C. A. and B.]

PUBLICATIONS.

One of the most attractive calendars of the year comes to us with the compliments of the Toronto Radiator Co.

The National Builder Publishing Co., Chicago, has just issued the third edition of the American Glossary of Architectural Terms, illustrated by Geo. O. Garnsey. Price $2.00.

A very interesting and useful treatise entitled "Wire; its Manufacture, Antiquity and Relation to Modern Uses," has just been issued by the B. Greening Wire Co., of Hamilton, Ont. The same company has also issued a handsome calendar on the back of which is a table of the size, length and strength of wire.

There has just been published by Wm. T. Comstock, New York, a valuable book of 116 pages entitled "Practical Paper-hanging," a hand-book of paper-hanging and other materials, by Arthur Seymour Jennings. Price $2, postage free.

"Architectural Rendering in Sepia," by Frank Forrest Frederick, Professor of Industrial Art and Design, University Illinois. Illustrated by full page plates, reproduced from water colors by the photogravure process, together with descriptive text. The rendering of architectural perspectives in color is now coming largely into use, and the publication of a practical work on the subject will be appreciated by architects and draughtsmen who wish to obtain those results of light and shade that cannot be produced in a line drawing without a large amount of extra labor. Bound in cloth. Price, $3.00. Wm. Comstock, Publisher, 23 Warren St., New York.

AMERICAN ARCHITECTURAL METHODS FROM THE STANDPOINT OF A CANADIAN.

By J. C. B. Horwood.

DOMINANT influences in architecture in all countries have, as a rule, spread from their largely populated and wealthy centres, and what is done in these may be taken as an index of the work of the nation. In the United States it will be found that this rule applies in the cases of New York, Boston and Chicago, the former being, perhaps, a mean between the two latter.

In no country or city, however, is work carried on under exactly the same system; and I venture to say that here in the United States their office methods are as varied as is the external character of their buildings; and while it is without dispute that there is work to be found here as bad, in fact worse, than in any other country, these remarks must be taken to apply to the better class of offices and the higher grade of work.

The methods pursued in these large cities are in a very great degree (though not wholly so) a system which has become necessary to meet the demands of such wealthy and fast living communities. No principals of a firm having a large practice can devote such a proportionate amount of their time upon each building as can be done in smaller cities, where the practice of the architect is much more limited, where more time is naturally given to the erection of their structures, and where the drawings are made by the ordinary office staff.

In these extensive communities there are always to be found a considerable number of migratory draughtsmen seeking experience to add to their store of knowledge; and it is comparatively easy to employ, at times, a sufficient number of these to assist in pushing to a hasty completion those extensive buildings which require such a large amount of labor concentrated upon them. (It is very amusing when seeking for a position to be frequently asked by one's interrogator whether he is a good man or not—a capable one—and should the applicant happen to possess some modesty in regard to speaking of his capabilities—recognized by us as a commendable trait—he must always avoid making a remark which might at all be transposed to mean that he was in some degree doubtful of his ability. Should he be so unwise as to thus commit himself, he would receive no further hearing.) Out of these professional nomads the more experienced are retained to become permanent assistants to take charge of the office work of any building under the occasional direction of the office supervisor.

In making the drawings of a large city building the following is somewhat of the general mode pursued:

After the architect has decided upon the plan roughly drawn to scale (perhaps upon paper ruled in squares an eighth of an inch each way) it is given to a competent man—the one usually who will have the work under his care should the building be erected—to lay it out to, say, an eighth scale. While this is being proceeded with the architect may be occupied in working out in a similar rough manner the elevations which he had in his mind while blocking out the plans, to hand over to his assistant as he did the latter; for in those lofty buildings, the plans of the several floors above the street level being practically the same, because the points of support must necessarily be continuous from foundation to roof, it is not therefore very often necessary to work out both plan and elevation simultaneously. To find the thickness of the walls it is but necessary to turn to the building law, as these dimensions are there regulated by the height of the wall. While these drawings are in progress the "practical man" or "engineer" is called upon to look into such matters as the sizes of columns, piers, girders, and any special constructional problems which may need to be solved in carrying out the proposed scheme, as well as to the position of boilers, engines, and the many apparatus which have become the necessary adjuncts of such buildings. When these preliminary drawings are nearing completion, a perspective of it is often outlined, (perspectives are sometimes worked out upon an ordinary piece of paper and afterwards transferred to the sheet selected for the finished drawing) and if there is not a draughtsman on the staff whose chief duty is to finish this class of drawing, it is sent out to one of the many well known men whose special line is to do this sort of work. Of late the colored drawing is coming very much in vogue, as can be noticed particularly in the exhibitions which are being constantly held; the chief reason evidently being that color is found to possess more points of attraction to the eye of the client than the drawing rendered in pen and ink. Should the erection of the building be decided upon, a similar mode of operation is again resorted to, and the weights of floors, walls and piers, are now carefully calculated to obtain the dimensions of the latter, and to make a proper plan of the foundations; girders, beams, and columns are accurately figured, and every point of detail, both in plan and elevation is most thoroughly worked out to large scales by the chief draughtsman, assisted by his less experienced associates, while the former is always working under the direction of his chiefs.

In order to facilitate the completion of a set of plans it is the general practice after the principal floor or elevation has been outlined on stou paper, to work the others from these on transparent paper or tracing cloth, all changes and rough studies of the various parts being made upon simila material—a practice well worth adopting. When all are completed, the juniors trace them in ink for the various processes of reproduction. Severa sets are obtained, and afterwards colored if the print is black and white. I have never yet seen a set of plans inked in and colored on paper for contract drawings as is our custom.

In New York the large ironwork firms do a great deal of their own detailing for constructional ironwork from general scale drawings given to them by the architect, which details are submitted for approval or correction to him before proceeding to carry out the work.

It happens that under this office system young men are kept almost continually at such work as their shrewd overseer perceives they have the most aptitude for, so that they may be of the most pecuniary advantage to their employer. Thus one may be kept altogether working on sketch plans or perhaps tracing the work of better men, or figuring up the weights of walls, piers, columns, etc., or working out the strains in beams and trusses; others may be chiefly occupied in making drawings for foundations after other men have made the plans of the floors above and the elevations have been decided upon; while still others may be confined to general details, or may work wholly on inside finish. So the work is divided for each to carry his branch to the highest point in the shortest possible time through working entirely at one sort of work, and so producing the architectural specialist so often found in the more populous American cities. Hence it is not difficult to find numbers of men who are exceedingly good on some branch of work, while on others they are as dull as the first year student of our Canadian offices; their ability on the one hand being in strange contrast to their dullness on the other. In illustration of this I may say, that I have met draughtsmen quite expert on working out the plans of tenement or apartment houses, and receiving a considerable remuneration for their services, who seemed to know scarcely anything about making a full size drawing, and who would be as much out of their sphere in making the drawings of a house in an open lot as they would be at the large detail. But the man who has been wise enough to show himself very apt upon such branches of work as he desires to pursue to his own advantage, and has thereby in spite of restrictions succeeded in obtaining a wide experience by his going to and fro, is one that is always in demand when there is any important work in progress. While the ordinary office education of young men is therefore of considerably more limited scope than I think is the case in Canada, yet this is being obviated in some measure by the excellent opportunities afforded by the architectural schools, which give their pupils a general all-round training previous to their being brought in contact with the restrictions of this system of office routine. I once heard one of the professors of the foremost American architectural college say that no better training in proportion and refinement can be had for the eye, in addition to the study of the "orders" than a good drilling in drawing from the cast; and this is becoming more than ever a prominent part of the course of instruction which a pupil receives at these places. A good education will not accomplish much if there is not a great deal in a young man, yet when there is, tuition will bring it to its greatest possibilities, and the result of this is seen to-day quite plainly by the work of the best trained men exerting a very great influence all over the country upon the work of their less fortunate confrères.

One decided advantage which accrues to a draughtsman in these large offices is the frequent occurrence of detail drawing of good and elaborate work, and I cannot help but think that if we Canadians spent more time in training ourselves in ornamental work in order to have it, as it were, more at our finger ends, notwithstanding the somewhat limited expenditure of our clients, we would find it easier to occasionally introduce it in our work than when we neglect our education in this respect, and consequently too often pass the matter over by concluding that it is altogether because we have not the money to spend upon it. Yet let us ever remember that as the enrichment of a piece of detail work brings it more prominently before us than if left plain, there is therefore the greater need of the whole work being good.

These remarks are not intended to imply that a piece of work well studied in relation to voids and surfaces does not very often look infinitely better than many a highly ornamented building not so studied. As a matter of fact there is a red brick printing house on Lafayette place, New York, which certainly belongs to the former class, and everything has been so thoroughly studied and made appropriate to its position, that it has become to the writer one of the most instructive buildings he has ever seen.

I was greatly surprised to find such an amount of rivalry existing here between professional men. The principle upon which business is apparently carried on is the "sponge" principle—absorb all you are able and refrain from giving to others all you possibly can—in the race to climb above your fellow and score a point ahead of him. It is this spirit which no doubt led them while formerly restricted at home, to ransack every country for ideas and suggestions to modernize and produce from them something beyond the attainments of their professional competitors. Even their own journals, which Canadians prize so much—too much I think at the expense of others—are scarcely ever looked at for suggestions when a problem is under consideration; in fact no instance of this has ever come under my notice in the better class of offices. The idea seems to be to get the home productions to know what you will have to avoid and surpass, while on the other hand illustrated books, and elaborate plates of European buildings from practically the time of the ancient Greeks are eagerly purchased in the rush for old ideas to be transformed and made new.

In reference to this matter of foreign illustrations, I have seen one of those exceedingly simple, and at the same time, exquisitely tasty French domestic buildings of the twelfth or thirteenth century—which would unfortunately be put aside by some of us as too unsuited for modern work—serve as the keynote for the design of a block of modern houses which would be a credit to any city in the world. In this respect it would be well that we were more like the Americans, in that instead of so often reproducing the works of others, we more often adopted the modes of procedure which have enabled them to produce such excellent results.

When we consider the architecture of the two countries and find that the difference between them is so very slight, we will be forced to admit that in some respects we are very fortunate, but in others quite the reverse. The former, because it is good for a people to enjoy the benefits which have come to its neighbor through their enterprise and industry, the latter on account of the natural inclination of the less self-reliant one of more limited means to rest too much upon the attainments of the larger and more progressive, rather than to seek from them suggestions to facilitate their own self-development. I am persuaded that this is a failing of ours, though there may be considerable cause for it, for being comparatively limited in our wealth and at the same time contiguous to one of the richest countries in the world, and being within easy reach of their principal cities, we have accustomed ourselves, till it has become a habit difficult to break, to go no further than these in our researches for material to awaken new architectural thoughts and inspirations within us when a world lies before us. The American was never similarly situated, and not being able to look for suggestions to his immediate neighbors, he was forced to go abroad in search of them. Not being entrammelled with the prejudices and jealousies which European countries are necessarily heir to, he was comparatively free to seek from all of them those hints and ideas which became to him an incentive to produce through their aid something distinctively his own; and it is chiefly to this fortunate position in which the lot of the American people has been cast, that I attribute their success, rather than to any inherent superiority over their northern neighbor or the foremost nations of Europe. Should we still persist in not being wise enough to follow their example in respect of gathering information from all countries, my fond hope is, that by some means, if not through a rigid commercial policy, they (the Americans) may at last succeed in forcing us to awake to the fact that besides living in America we live in the world. May not our Provincial Associations which have already done such valuable work, go still further by turning the mind of the rising generation under their care in this direction, and good shall certainly result from it both to themselves and their students, and hence to the country at large. One of the most noted writers of the day has made the assertions, "There is no art among a shepherd people if it remains at peace," and "There is no great art possible to a nation but that which is based upon battle." In this late age, if this be true, we would not wish to purchase art, no matter how desirable she may be, at so great a price. Upon close examination of these statements it will be seen that it was not exactly war that produced art, but as war was essentially the ancient means through which one nation after another sought and succeeded in asserting its superiority over its neighbor, it therefore afforded the opportunity for the development of mind, character, and individuality which would otherwise have remained dormant and unexpressed, as in the case of the contented shepherd in the presence of his well-favored flock upon the grassy slopes of his native land.

But the methods of mankind are changing, and that contention and rivalry which has long since become second nature to most of us is now being gradually transferred from the more repulsive occupation of killing each other, to the more peaceful, and at the same time more profitable—the industrial and commercial. Should these eventually become *the* means, or some of them, through which national rivalry may be carried on to an almost unlimited extent, may we not expect to see similar results from peoples so exercising themselves as was developed by the methods now happily becoming things of the past? Is it not worthy of note that the American nation which is being recognized on all hands as making the greatest progress in architecture and exhibiting characteristics in its work said by those who know best to be elements of a new style, that they should be par excellence the people who are seeking, by constant and most strenuous efforts in the industrial and commercial spheres, to climb above all other national competitors? Turning at once to ourselves (for it is more profitable to speak of our failings than to dwell on our excellencies, though they be many) what a strange contrast we behold. How often we see in our daily papers the assertion that still more intercourse with the United States—some even going so far as to say complete subjugation to them—is the panacea for all our ills; and some business men have been very much disposed of late to place a premium on American architects by engaging their services when any work of importance is under consideration. What wonder then is it, that if some of our fellow countrymen exhibit such an unfortunate bias of mind in this direction, that many of our important buildings should express the same?

We need to be weaned from all such habits of thought, and to awake to a consciousness of our positinn as a nation, and our value to, as well as our dependence upon, the other countries of the world. I am fully convinced that never till that is accomplished within us, and it has become a habit of our mind to think thus broadly, can we have work which will possess a distinctively national mode of expression, and which shall thereby be of such a character that other peoples will study it with profit as they have studied American architecture.

CHARACTERISTICS OF ARCHITECTURAL STYLE.

By G. F. Stalker.

(*Continued from page 120.*)

In the preceding papers on this subject it has been shown that the chief characteristic of what is commonly known as ancient architecture was horizontality; although some architectural forms which became the dominant features of subsequent styles were not unknown to the ancients. The pointed arch, for example, was used by the Assyrians and the Greeks (the joint being horizontal instead of radiating as in Gothic times) and the semi-circular arch was a very marked feature of Roman work. But it was not until the fourth century of our era that a transition took place that led to the gradual, though ultimately complete, abandonment of classical forms, both as regards design and construction. Strange to say, that, whereas architecture is the outgrowth of man's necessity to erect for himself a suitable place of shelter and abode, religion has always been the chief factor of its development. Among ancient examples, indeed, there are few remains that are not either wholly or to some extent ecclesiastical edifices. Of palaces even there are few remains, and of defensive works fewer still; while, until we come to the Roman period, we have no examples whatever of civil architecture. And if more attention has been given in medieval and modern times to the treatment of our domestic and civil buildings, it is none the less true that the greatest amount of talent has been bestowed and the largest amount of money lavished upon our cathedrals and churches. So much has this been the case, throughout the whole history of architecture that the features which have dominated in the ecclesiastical buildings of any age, have been transferred, in a modified degree, to all other buildings of that time. But, it is only fair to say that, so far as can be judged from the few domestic remains of the ancients, there has been much greater diversity of design in the treatment of buildings of a non-religious character since the days of the Romans than there was anterior to them. The same feeling, however, that influenced the nations of antiquity to produce their mighty and glorious temples, was the motive power in the early Christian centuries that brought about the transition from the Roman to the Romanesque in western, and the Byzantine in eastern Europe, and that led ultimately to the Pointed Style becoming par excellence the Christian style of architecture.

Until the fourth century it was not safe for a man to be known to be a Christian. The new religion had to be propagated in secret. Caves, tombs, catacombs, anywhere away from the haunts of men were the places selected for the meetings of the early Christians. And it was only after Rome had tried ten times "to extirpate the vipers" that the Emperor Constantine embraced Christianity, and not only gave freedom to the Christians to worship according to the new faith, but extended to them the protection of the very power that had formerly oppressed them. Coming out of their hiding places, and without the means to erect suitable buildings for themselves, they made use of such as were already in existence. And, though these buildings had been erected for a very different purpose than for places of worship, they were found so admirably suitable in this emergency, that, with slight modifications, they became the type of the cathedrals and churches from that day to this. The Roman Basilica was originally intended to serve for a variety of purposes. It was a business exchange or mart, a court of justice, a fashionable promenade, and a general meeting place for all and sundry. In plan it was oblong, and generally divided into three spaces by two rows of columns running longitudinally, the central space being wider than the other two. The entrances were at one end of the building, and at the other end was the judges' tribunal. It was in these buildings that the first public assemblies of Christians took place, and it will be at once apparent to everyone that the plan of the Basilica, having been found so convenient and suitable, rooted itself in their minds so firmly, that, in the main, it was adopted as the plan for the churches which were subsequently erected.

But though there has been practically no change in the general features of the plan, except what is due to more or less elaboration in aisles, apses or other arrangements, the design and construction were from the first subjected to modifications, and a departure from the original having been made, the gap was gradually widened until an entire separation was effected, and a new style invented. The initial tendency of the transitional work was towards the elongation of the vertical lines. And herein lies the most striking characteristic difference between the styles of architecture before the fourth century, and those which have come into existence since that time. The columns were attenuated so that the relation of diameter to height was entirely severed, although for a time the details of capitals and bases underwent little or no change. Then the desire to obtain height necessitated the abandonment of flat ceilings, and vaulting was substituted. The Roman entablature, which, in the earlier Romanesque buildings, had been carried square across the capitals of the columns, disappeared in the later work; and the semi-circular arch, though with classical details, took its place.

While this was proceeding in western Europe, Constantine, having removed his seat of government to Byzantine, was busily endeavoring to make his new capital surpass the old one in magnificence. He erected many buildings for a variety of purposes, in the execution of which artists from all parts of the world, but especially from Greece, were engaged. The essential features of Byzantine architecture did not differ materially from the Romanesque, but in detail and decoration there was greater refinement and variety. But that for which the architects of eastern Europe were chiefly distinguished was their invention and use of the cupola or dome. This was not only a striking departure from the practice of their western brethren but a most valuable and imposing addition to their buildings, both externally and internally. It opened up almost endless possibilities, and it has been taken advantage of and developed throughout the succeeding centuries.

Justinian was even a greater builder than Constantine, whom he succeeded; but with the exception of clothing his buildings with greater elaboration of detail, and more costly materials, and an almost Asiatic gorgeousness, he did not carry the salient points of the Byzantine style of architecture any further than his predecessor.

Rome had by this time been overrun by the Goths from the north of Europe, and had suffered the fate which generally goes hand in hand with conquest, in having most of its movenble art treasures removed, and many that would otherwise have remained to this day, destroyed. But the savage invaders were in time brought under the influence of Christianity, and out of the general chaos a purer, more perfect, and more distinct style of architecture than any that had existed since the last days of the Romans, grew up and spread over nearly the whole of Europe.

For a time the semi-circular arch was continued, but the mouldings and other details by which it was enriched had clean cut the connection with classical precedents. In some respects the massiveness and solidity of the buildings of this time remind us of the work of Egypt and early Greece. It seemed as if the builders had returned to the first principles, and, for lack of more scientific knowledge of construction, were determined to make their building safe by an abundant use of material. But apart from this there is a sturdiness and force apparent everywhere in the general design. This is hardly to be wondered at when we consider the character of the Northmen or Normans who took the lead in this new phase of architecture. They were a hardy fighting race, and probably associated with all their buildings the idea of defence in addition to that for which it was erected. The plan of the Basilica, which has been referred to, had been slightly modified by the Romanesque and Byzantine builders. They had given greater prominence to the place of the judge, so that it became the apse of their churches; and they had taken down the side walls for a certain distance from the apse and extended their buildings in a lateral direction therefrom, and so formed the transepts. It was at the intersection of the transepts and nave that the Byzantine architects constructed their domes. At the same points on the plan the Normans carried up a square tower. It was not an uncommon adjunct to a basilica to emphasize the entrance end of the building by the erection of towers. These were also incorporated into Norman work. But though, in a general sense, the plan remained unchanged, the whole character and detail of the buildings were simpler and bolder than the classical original, and more homogeneity of growth from one part of the building to another.

But the tendency towards verticality soon led to the change from the semi-circular to the pointed arch, and this then became the characteristic feature of the style. As is well known the name "Gothic" as applied to architecture was at first a name of opprobium, and the style is better described by the name "Pointed Architecture" than by any other. Various designations are applied to this style, but as they refer more to dates, and localities, and reigns of monarchs, than to any inherent difference in the style itself, it is unnecessary to refer to them here. The one great characteristic which runs through the whole work in this style is verticality. The columns are in most instances of immense height as compared with their diameter and of a great variety of kinds: circular, square, octagonal, clustered, and so on. Neither was there any rule for striking the arcs which formed the arch, it was enough that it was pointed.

With the change to the general adoption of the pointed arch, however, came also much greater refinement of detail and elegance of construction. The vaulted roofs with their innumerable intersecting ribs were worked out with the greatest skill and mathematical precision; and the decoration was chaste, simple and effective. The somewhat squat looking towers of the Norman period gave place to most graceful towers and spires rising to immense heights, and the openings, which at first had been small, giving a somewhat dismal light to the interior of the buildings, were gradually enlarged, until it may be said that the entire space between the buttresses was occupied by windows.

With the invention of painted glass a great leap was taken in the matter of ecclesiastical decoration, and, if the kind of glass that is used in a building is sometimes considered a matter of little importance, it had a mighty influence on the development of the Pointed Style in the middle ages. Some writers have gone so far as to say that, next to the necessity that may have existed for having churches, the buildings were designed as frames to receive painted glass windows; and in those days, when the masses were wholly uneducated, they served an excellent purpose, in addition to the great charm they added to the entire composition. The mural decorations of the ancients, though executed in the costliest materials, are altogether eclipsed by the glass paintings of the twelfth and thirteenth centuries. But in addition to their intrinsic beauty they were highly educational, in so far as the wonderful story of Christianity was made the very medium through which the light was admitted to their church buildings.

With regard to the buildings of a non-religious character that belong to the Pointed Style, it is hardly necessary to speak at any length. As has already been suggested, there are more examples of this class of structure, treated with greater variety and appropriateness for their manifold purposes, belonging to this style of architecture, than to any other known to us. But the leading characteristics of the style are apparent in a greater or lesser degree in them all. The purposes for which such buildings were erected suggested such treatment at the hands of architects as was necessary. At the same time it must be said of them, that the religious feeling was always more powerful in drawing out the noblest thoughts in artists in this, as in all other lines, and so we find the highest points of excellence in architecture attained by the ecclesiastical edifices, the buildings for other purposes being in every case secondary to them.

After the fifteenth century the spirit of architecture seems to have taken wings and fled. For though there have been many and great buildings erected since that time there has not been anything that can be properly designated as a new style of architecture. And in these papers nothing has been said of Indian, Chinese or Mexican architecture, for the simple reason that the styles of those countries, however beautiful in themselves, do not directly affect us.

Correction.—In last paper of above series, page 120 of Canadian Architect and Builder, 9th line from close of article, for "From first to last experience," &c., read "From first to last extravagance was the order of the day at Rome."

NOTES ON QUEBEC ARCHITECTURE.

NOT only the form of primitive buildings, but also the materials employed, it has been said, were affected by the climate and surrounding circumstances. Such must have been the case with our predecessors in this ancient city some seventy or eighty years ago, as it is evident they respected not a little the rigors of the climate when they universally adopted the steep pitched roof, carefully avoiding parapets, projecting cornices, gablets, or in fact any ornamental or constructive hindrance to the free passage of snow from the roof to the street below. To the tyrannical demands of climate they sacrificed everything but the strictly needful, their great aim being to make their roofs water tight beyond a doubt, and the house in general to be easily warmed. By thick walls, small door and window openings, low ceilings, and "double windows" set flush with the outer face of the walls, they sought to accomplish the latter end, and in so doing yielded to the imperative demands of climate, and proved that, as in the far past, so then, architecture had to bow to the influence of climate. Less now, however, than then, is this influence felt, for in those days the box stove in the hall with a plentiful supply of good hardwood had to do duty for the whole house, and although it was a cheery sight to see the bright glow of the fire and listen to its cheerful roar as the noise of ice-cracks without sounded loud and often, yet the far away corners, and the rooms not in daily use, were far from possessing the genial and pleasant temperature of the modern house heated by a "Daisy," a "Gurney," or other equally good hot water boiler, and its circulating pipes or radiators.

Then in the use of rubble masonry we are reminded of the proximity of the Beauport and Chateau Riches quarries, and the regiment of masons residing in those parishes, combining with their trade the avocation of farmers. Material close at hand, and labor to be had cheap by employing the farmer-mason had its effect, and in many of the old time plain (to a fault), but yet comfortable old homes of Quebec, a striking proof is obtained as to the truth of the statement that architecture is greatly influenced by climate and surrounding circumstances. Such houses as are now alluded to are to be found in St. Louis, St. Ursule, D'Auteil, Couillard and other streets within the city walls. The wooden Doric or Ionic pilaster on either side of the entrance door, with its entablature, frequently ornamented, was the usual embellishment indulged in; the irregularities of the rubble masonry forming the walls is generally found transformed into rectangular blocks by the use of raised mortar joints, and the whole surface then painted.

In many of the houses of this period may be found some rather elaborate wainscotting in pine, but unfortunately always painted, the framing generally moulded on the edge, the panels having chamfered edges and the centres sometimes raised; curved heads or quarter round corners to panels frequently occur; small dentils in the cornices were also very general. The houses erected about this time in the Lower Town, and being the residences of the merchants of that time, frequently had vaulted basements of very substantial construction; many of them still exist, and form excellent wine vaults.

Succeeding the foregoing type of house, a more modern class of building followed, the steep roof and flush double windows being still retained, but with fine-cut ashlar front and larger openings, metal roof instead of the old-time wood shingle, loftier stories and higher basements, a distinct change was made. Symmetrical these houses certainly were, but so much so as to stamp them as being cold and tasteless. A few honorable exceptions are to be noted on St. Denis St. Cape, where some of the former merchants of Quebec have built homes for themselves in a more ornate and more costly style.

Within the last fifteen years the taste for modern houses has greatly developed, so that now in all directions residences of good design are to be met with, combining therewith most of what is generally known as "modern conveniences." In not a few instances elegant residences have been erected on the Grande Allee and other fashionable streets. Nowadays all the comforts of hot-water heating, electric lighting, and sanitary plumbing of handsome make, with the elegancies of hardwood finish, tiling, stained glass work, etc., etc., are generally looked for. The effect of all this is, that the old house of 70 or 80 years ago is looked upon with but little favor. Yet in these latter we find that regard paid to climatic demands which it behooves the builder of the present day to meditate upon, and it would be well for him to evolve therefrom a style of building which, while retaining all desirable points in connection with the requirements of climate, might with tasteful handling incorporate the good points of modern building, and out of the whole produce a type of architecture, "Quebec" in character.

These notes must not pass unmentioned the wonderful difference between Quebec's business premises as they are now and as they were 50 years ago. Then our wholesalers occupied, generally speaking, either former dwelling houses or stores built of timber on the various Lower Town wharves—low, dingy structures they were for the most part—that is, the wharf stores—besides being twisted and distorted by the settling of their foundations. A few still remain, serving to emphasize the great progress made in this direction when they are compared with the warehouses of the Thibaudeaus, the Hamels, and notably with that recently erected by Hon. P. Garneau, and that erected by Mr. Paquet—the last named handsomely ornamented by polished granite shafts in all its six stories.

In churches and public buildings too, one may observe a great advance in taste and in conception of the fitness of things generally, so that it is safe to affirm that within the next fifteen or twenty years there will be still more marked improvement, and a still greater effort to introduce modern ideas and features into our buildings, which may be done or ought to be done, without flying in the face of the conditions of our climate. In one direction a marked improvement may easily be brought about—do away with the outer winter sash and substitute therefor an inner sash, which will answer the purpose just as well, and leave the jambs free for architectural treatment, and to be seen the whole year round. As it is, for six months of the year the double window conceals, or at all events greatly detracts from, the ornamentation of our windows by being placed in front of the same.

While admonished by the peculiarities of our climate not to indulge in those pleasing effects of roof treatment which in practice result in leaking roofs and damaged walls, with endless repair bills, yet neither is it necessary that the eaves line should be entirely unbroken and without architectural effect, giving a "squat" and unfinished appearance to the building. By always keeping in view the need of liberal space for the moving off of ice and the avoidance of snow catchers, and by taking needful precautions to prevent the freezing of water at the eaves by deafening inside or by making a double roof, the architect who has had experience in this climate should be able to solve the problem of meeting the exigencies of the latter, whilst he produces a design not entirely devoid of picturesqueness.

The Quebec architect should build, not because this or that style is fashionable, but with proper regard for the requirements of climate and surrounding circumstances, produce such a style of building as will without question assert itself to be of a type suitable to the climate and other conditions of the locality in which it stands. This, the old buildings of Quebec did; let us not despise them, but so improve them and embellish them and adapt them to modern notions, that in the new production we shall have, if not a national, at least a local style of architecture.

CANADIAN BUILDING STONES.

THE variety, value and extent of building stones in Canada, appear to be but imperfectly known. With the view of adding to the existing information on the subject we print below particulars regarding some of the principal quarries.

THE OWEN SOUND STONE CO.

Until within a comparatively few years the demand for stone in Ontario has not been very great, caused to a certain extent by the very small proportion of good stone which has as yet been revealed in the Province. The freestone used in all large buildings of our towns and cities was brought from a distance of hundreds, sometimes thousands of miles, and at such a great expense as to almost utterly preclude the use of freestone in any other than small quantities or on works of the most expensive nature. This undesirable state of things has at last ceased to exist. In the township of Mono, county of Dufferin, some three miles north of the town of Orangeville, the Owen Sound Stone Company acquired a tract of land about three years ago on which there is a deposit of as good sandstone as is obtainable anywhere. This quarry they have been developing and putting into shape since then. They now have one of the best equipped freestone quarries in America with unsurpassed facilities for the handling, shipping and transportation of their stone.

The sandstone deposit is 16 feet thick, from which blocks of any size up to the capacity of machinery for handling can be taken. Overlying the sandstone there are some four feet of well bedded blue limestone in beds of six inches to two feet thick, and well adapted for footings and heavy foundations and heavy masonry of all kinds. The sandstone is a grey or olive shade, bleaching on exposure to a magnificent white, which experience has shown does not discolor, as do a great many of our high-priced imported stones. This stone also hardens by exposure, there are no flaws or drives, it is easily worked, and is, in fact, a nearly perfect sandstone. Experts pronounce it equal in every respect and superior in a great many ways to the very best freestones hitherto in the market. The quarry can furnish almost anything in the line of stone suitable for heavy and light work of every grade. It has a present working face of between 500 and 600 feet, which is being gradually extended. Eight derricks, two planers, one set saws, all run by steam, are employed. The company intend putting in channelers next season.

During the past season they have been busily engaged in building a line of railway to the quarry. The line which is now finished is according to the main line standard and four miles in length. Starting from the C. P. R. station at Orangeville, it parallels the main line for a short distance and then curves off towards the quarry. Some heavy work had to be done in the shape of heavy filling, rock and swamp grading, and there is one immense cut at the quarry end of the line. Adding to this two large trestle bridges and several small pile bridges one has some conception of the magnitude of such an undertaking in the hands of a private company. The construction of this line involved the expenditure of some $35,000, but the quality of the stone and the certain prospect of a very large and lucrative business prompted the company to take this means of placing the product of the quarry on the market. The track now runs along the whole front of the quarry and all stone is loaded directly on to the cars. Two sidings have been provided for extra accommodation and a piling ground for the storage of surplus stone of different kinds is served by two extra derricks. The company have recently bought several acres of quarry land in addition to their original purchase, and intend this winter erecting a large boarding house and cottages for the proper housing of their employees.

Though business has been comparatively dull for the last year this stone has been gradually but surely establishing itself and proving to practical men that the long felt want of a first-class native sandstone is at last supplied, and the Owen Sound Stone Company feel assured that the more dealers and the general public become acquainted with the stone the less foreign stone will be used in the Province. This company has also grey limestone quarries at Owen Sound and a quarry near Inglewood on the Credit Valley branch of the C. P. R. For the last five years the Owen Sound Company has been engaged in building as well as selling stone. For several years they had from 300 to 600 men employed in excavating and building railway work in different parts of Ontario. Amongst other works which they undertook and completed in a satisfactory manner were the Sherbourne street and Rosedale bridges in the city of Toronto, the masonry for the Belt Line Railway, the large bridge over the Thames at London, some two miles of bridging and culverts comprising all the foundation and dimension masonry for the C. P. R. Company's extension across the Don flats, the immense shops at Toronto Junction and some thirty or forty bridges and culverts on the Credit Valley, Ontario & Toronto G. & B., all for the C. P. R. The great bulk of the stone used in these works was taken from their great limestone quarries at Owen Sound, which has no superior anywhere for this class of work.

THE LONGFORD QUARRY AND LIME CO.

The Quarries of this Company are situated on the shores of Lake St. Johns, in the township of Rama, County of Ontario, and the Company's address is Longford Mills, Ont. The formation of limestone from these quarries is very fine, the beds of each layer of rock being exceedingly level and but very few dries or cracks appearing in them. The color is of steel grey when first taken out of the quarry; after being exposed for some time it becomes lighter in color, and its general appearance is then almost like marble glistening with glass. The thickness of the different layers of the strata runs from 5½ inches to 16 inches, but the finest layers work splendidly to 12 and 14 inches, while the 5½ inch bed cuts into window sills and heads.

The facility for shipping is all that could be desired, a switch off the main line of the G. T. Ry. (Northern Division) enters the quarry and large and convenient derricks are placed so that a large quantity may be loaded every day.

The company have been fortunate in tendering for many large contracts for their stone, and refer the building trade with satisfaction to the following structures which have been supplied by them; The palatial residence of Mr. S. H. Janes at North Toronto, the foundation for a large part of the New Victoria University, the Freehold Loan Building, the New Drill Shed, the New Court House, the Confederation Life Building, the new Athletic Club building, the center pier of the King Street Subway, all in the City of Toronto. They also furnished a large quantity of foundation stone for the Edison works and Peter Hamilton's large warerooms at Peterboro', Ont., also a large quantity for decorating around windows and doors of St. Joseph's R. C. Church in the township of Douro, and have just completed shipment of the decorative pillars and fence around the Customs buildings in Peterboro', which adds very much to the general appearance of that handsome structure. The magnificent new post office at Orillia has all its stone work from these quarries. The company is composed of Messrs. William and George Thompson, of Orillia, Ont. (the well known and pushing lumbermen of Longford Mills), Mr. Andrew Craig as manager, who is considered to be one of the best quarry men in Ontario, and Mr. Maxwell Hall as secretary treas. With the record of the past and the business ability of the members of the company, the building trade have a guarantee that any business entrusted to them will be carried out in good faith.

The company believe in advertising, and in order to bring their material before the public they erected a beautiful monument with a piece of wall at the exhibition grounds at Toronto during the past season, and now with pleasure refer the trade to their advertisment in the columns of this journal.

MIRAMICHI STONE.

About two miles below Newcastle, New Brunswick, on the Miramichi River, is situated the historical French Fort Cove property, comprising about twelve hundred acres, owned and occupied by Mr. C. E. Fish. The place derives its name from the fact that many years ago, when the French occupied this portion of Canada, they erected at the mouth of the Cove, a stone fort which was afterwards destroyed by the English. Just inside the Cove, and extending at least two miles up the bank, are almost inexhaustible beds of Freestone, suitable for building stone, bridge stone, and abrasive purposes. The deposit is regular, ranging from twenty feet down to thin sheets, and is probably the most extensive deposit of sandstone in Eastern Canada. Like the sandstone deposits in all districts, it varies in fineness, color and density.

The building stone, known as "Miramichi Stone" (Miramichi meaning "happy retreat"), is of a rich olive color, and possesses all the merits of a first-class structural material. It is easily worked and long years of exposure have failed to change its color or density.

The "Langevin Block" in Ottawa, New City Hall in Hamilton, Ont., the residences of Messrs. James Ross and Duncan McIntyre, in Montreal, are a few of the buildings more recently constructed entirely of this stone. The coarser grades have been largely used for bridges, culverts, docks and general foundation purposes under water. It is particularly well adapted for paving purposes, its grittiness giving a good foothold which its hardness prevents wearing smooth, and its non-absorbent qualities render it capable of shedding ice and snow readily. There is also a good grindstone and wood pulp stone quarry on the property, but as yet it has only been worked on a small scale.

The quarry is equipped with modern machinery throughout, and has good shipping facilities by rail or water. Mr. John Laurie, 162 St. James Street, Montreal, is sole agent for the quarries.

A FINE QUARRY.

What is now said to be one of the best stone quarries in the Dominion and perhaps on the continent, is situated one hundred and forty miles below Quebec, three miles from Trois Pistoles station on the Intercolonial Railway, which is also on the St. Lawrence River, thus affording facilities for shipping by rail and vessel.

The quarry is a mountain of red sandstone of the most beautiful color and of the very best grain. It covers an area of about two miles long by half a mile broad, and ranges from about twenty to one hundred and fifty feet high. The property was acquired from several farmers by Mr. F. G. Dubé, of River du Loup, Que., a couple of years ago. Mr. Dubé, although a very enterprising gentleman, was not able to go into the working of the quarry on account of ill-health, and to the regret of his many friends died in May last, leaving this magnificent property without realizing anything from it himself. Samples of the stone were sent to New York, Boston and Montreal, where it was recognized by connoiseurs to be of a superior quality and color. It is claimed to have many points of superiority over the imported Scotch stone, as it is acclimated to our country and will not be damaged by exposure to the weather, but instead will increase in strength with age. It is of a very close and compact grain, and can be cut to any shape desired. When fresh from the quarry it is soft and easy to work. A sample which was lately sent to this office justifies the superiority in character claimed for this stone. We understand that this quarry will have to be sold to close the estate of the late Mr. Dubé. This ought to prove a rare chance to some one interested in the stone business.

CANADIAN GRANITE CO.

This company own an extensive granite quarry at Kingston, and works at Ottawa, Ont., where every description of marble and granite work required for architectural purposes is manufactured.

THE ONTARIO ASSOCIATION OF ARCHITECTS.

The coming convention of the association, which will take place on February 7th and 8th, will be the most important that has been held. In response to a request sent out by the Registrar for suggestions on the part of the members as to questions to be discussed at the coming convention, many answers have been received suggesting points for discussion which will amount to a review of the state of the Association. As this will be a critical point in the history of the Association, there ought to be, and probably will be, a full attendance of members on the first afternoon, when this discussion will be opened. The second day's proceedings will consist of testing the strength of materials in the testing machines of the School of Practical Science, papers by members eminent in the profession, and the election of new members for the Council. The proceedings of the two days will, we understand, be concluded by a dinner on the evening of February 8th. We are given to understand that something of a surprise in the way of entertainment is in store for those who may attend the convention.

PERSONAL.

Mr. Wm. Stewart, architect, Hamilton, Ont., has admitted his son as a partner, the firm name being now Stewart & Son.

Mr. W. R. Gregg, architect, Toronto, has admitted to partnership his brother, Mr. Alfred H. Gregg. The title of the new firm is Gregg & Gregg.

Mr. Eustace G. Bird, recently a student in Toronto Architectural offices, has secured a position with Mr. Calcutt, a prominent London architect. It is Mr. Bird's intention next summer to make a tour of France and Italy.

Mr. Rutan, of Boston, one of the architects of the New Montreal Board of Trade building, recently made a thorough inspection of the work and pronounced himself well satisfied therewith. Mr. Edward Maxwell is the superintendent. The building is expected to be ready for occupation early in April.

TORONTO ARCHITECTURAL CLUB ORGANIZED 1889

PHOTOGRAPHY FOR ARCHITECTS.

WE herewith publish a paper on "Photography for Architects," by Mr. J. J. Woolnough, delivered before the Toronto Architectural Club, at its second meeting in November last, together with the introductory remarks of the President, Mr. Alfred H. Gregg. The paper was illustrated by photographs and photographic apparatus, and at the conclusion flash light views of those present were taken. The president in introducing the subject spoke as follows :

IT was suggested by several members of our Club that we devote one of our evenings to the study of photography. The task was then assigned to me, in addition to introducing the speaker of the evening, to dwell on the special advantages derived by an architect from the pursuit of this branch of art. The more scientific details of photography and the ways of working the camera will be taken up by our friend, Mr. Woolnough.

An architect should be not only a lover but a producer of the beautiful, and it should be his endeavor to raise the standard of art education in every way possible. That a camera will give him material assistance in emphasizing all these characteristics, it will be the aim of this paper to set forth.

His mechanical instincts soon give him the mastery over the details, and ere long he sees in the subject an art never before realized. The picture-making, the arrangement of lights and shades, the perspective, are necessary parts of the photographer's education, and as he delights in these he becomes more and more the devotee of art. Failure may follow failure, but perseverance brings reward, and soon he becomes a producer as well as a lover of the beautiful.

Let him walk forth some fine morning, leaving the turmoil of the city behind him. Close to its confines he may find innumerable signs of Nature's art—the noble trees, the hills, the rocks, the valleys with their trickling streams, the pebbly beach, the grand old sea, even the clouds in their billowy beauty—all scenes to be reproduced by his trusty lens, and soon by old Sol's kindly aid he becomes possessed of indelible mementos of his trip. To others his pictures seem a revelation, for none but a trained eye detects how much of the beautiful lies all around us.

But dearer to an architect's heart are ancient buildings crumbling to decay, with details over which days and weeks have been spent by skillful hands. Are these to be lost? Nay, rather let us train the rising generation to know and love the works of their ancestors. Truly, pictures are produced for the photographer, whichever way he looks. Take a street scene, for instance, in which some special grouping of figures has attracted his notice. Quickly he chooses the best position for his camera, composing his picture, with proper amount of foreground and background, and with accessories well distributed. It is thus that the photographer becomes the lover and the producer of the beautiful, and it is thus he may educate others to a better appreciation of their artistic surroundings.

But before deciding on the expenditure of one cent on the required apparatus, an architect would do well to make up his mind to two or three things. First, he should decide to do everything, from the exposure of the plate to the final printing, himself. He should not permit anyone to "do the rest" at any stage of his proceedings. Only thus can photography become of practical use. Just here let me say, that the uninitiated seldom dream of the pleasure to be found in developing. To take the cold white plate and by the application of a few chemicals to see the image gradually developing—if a landscape, to watch the one tree after another appear; or if some group of friends, to see the faces rising as if by magic until the perfect result is before us. The exposure is not by any means the most pleasant part of the process. There is then an omnipresent feeling of dread lest something has gone wrong. It is when developing that we are first able to judge of the actual success we have made.

But especially is it of advantage to be able to go through the whole process yourself, as by doing so one may easily obtain a finished print much more quickly than by employing a professional photographer, and that, too, without interfering with your business to any noticeable extent. Another word to would-be disciples of Daguerre—expect failures at first. With care they will become less and less frequent till finally they may be reasonably certain of success every time.

At the outset of this paper it was attempted in a general way to show how advantageous as an artist, trainer and art producer the camera may become. There are some more technical ways in which it will be found of incalculable service. First, for perspective work, in supplying trees, figures, etc., and in obtaining certain street views, that correct representation may be given of neighboring buildings, also in the study of sciography or the science of shadows. Second, in preparing measured drawings of existing work. Much labour may thus be saved in counting bricks, etc. Third, for use of the clerk of works. Views thus obtained would give correct representations to the architect of the progress of the work, and certificates could then be granted. Fourth and last, the collection of a series of photographs of his own designs and details, and of any architectural views which may be of interest to him.

To an Englishman, our Canadian climate seems an ideal one for a photographer. The clear atmosphere lasting from January to December should surely not be wasted.

But after all, there is another question which may be asked—can we afford it? I answer by asking—can we put our money to better use? Here we are, a gathering of architects and students, with wealth staring us in the face. Are we misers with hearts of stone and blood turned to ice, that we endure accumulating burdens of useless hoarded gold? Surely not! Let us be up and doing, let us rather meet the danger manfully, courageously, and, I may add, efficaciously, by throwing off these needless weights, by casting aside the carking care of a Crœsus for the glad, though perchance penurious, life of an amateur photographer. This may seem like levity, but seriously, be our savings great or small, we may with the initial expenditure of from ten to fifteen dollars, become possessed of a camera amply sufficient for all our needs. Our developing and printing outfits will cost but little more. All that is required will be two or three trays, a pair of scales, a ruby lantern—easily home-made—and a few chemicals, all of them cheap. For a dark room, the modern bath-room admirably fulfils all necessary conditions.

What more can I say to inspire you? Certainly nothing I can think of at present—for I would fain see every office equipped with this useful instrument. We are here to consider every means, great and small, for the advancement of architecture in our country, and if we can force the sunbeams to do more work for us, let us by no means miss the opportunity.

ALFRED H. GREGG.

MR. Woolnough was then called upon and read the following paper :

GENTLEMEN,—Before plunging into a description of photography, and how it is done, I should like to emphasize that part of our worthy president's paper, dealing with its practical use to architects. I myself have found photographs of old buildings very useful as an aid to memory, in preparing measured drawings. Furthermore, it must not be forgotten, that photography is not only one of the most fascinating and absorbing of hobbies, but that it requires for its successful working, those supremely useful qualities of patience, care, order, precision, close observation and thoughtfulness, which are, I believe, specially required by all architects who wish to ensure a successful career.

The production of a finished photograph can be divided into three heads: 1st, Exposure; 2nd, Development; 3rd, Printing.

Commencing at No. 1, The Exposure, you will require a camera, with lens, tripod and plate holder, also a focussing cloth, and lastly, the dry plates. The majority of cameras on the market are sold complete with lens tripod and plate holder. I will now unpack my set and explain the use of each part.

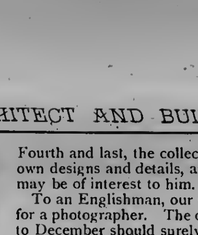


FIG 1.

On being the happy possessor of a complete set, of course there is an uncontrollable desire to set forth and immortalize some dainty bit of scenery, but it will be first necessary to fill the plate holder with two plates, and as the plates are extremely sensitive to ordinary light, this has to be done in a dark room, by the light of a red lamp.—red and orange light having (within certain limits) no effect on the plates. On unpacking plates and placing in holders, you will notice that the plates are sheets of glass, coated on one side with the sensitizing compound.

Going back to the camera, I will now take up and describe each part. Taking the camera first, it is absolutely necessary that it is light tight, with no pinholes in the bellows, and also its base should fit firmly and rigidly on top of tripod, so as to prevent all vibration. The bellows should be long enough to extend far along focus lens, and the base board should be of a length so as not to interfere with the use of a short focus lens (see Fig. 1). The focussing screw should be within easy reach, the front of camera being a very awkward position for it. Of more importance for architectural subjects are the facts that a camera must possess a swing back ; a

FIG 2.

rising front is also very useful. The necessity of a swing back comes in when photographing a tall building in a confined space, when it will be found necessary to point the lens slightly upwards so as to take in all the subject. With a *fixed* back to camera, the result of a picture so taken would be somewhat like Fig. 2, owing to the dry plate being out of upright. By having a swing back, the dry plate can be placed in an upright position, thus ensuring vertical parallel lines. This is a very important item. The rising front is a moveable board at front of camera, and on which the lens is mounted—this is useful for cutting off any excess of foreground ; a photo of a building with the roof line at top of picture, and about one-third up all foreground, gives a very unsatisfactory impression (see Fig. 3).

FIG 3.

Next to the camera comes the lens. Lenses can be divided into two classes, the *single* and the *compound*. The single lens is formed of either one disc of glass, or else two in optical contact. The compound lenses are formed of a series of two or three lenses fixed slightly apart in the one mount. The single class of lens is by far the cheapest, and for pure landscape work is all that can be desired, but for architectural subjects it causes a slight curving to all straight lines, especially those near the margins of a photo. The compound lenses of the rectilinear form are perfection for architectural subjects, but are rather expensive in comparison with the single class. I myself have always used single lenses, and find that the slight curvature given to some lines is hardly noticeable.

The focus of a lens, that is the distance of the lens from the focussing screen, varies according to whether the lens is a short focus or wide angle, a

FIG 4.

medium focus, or a long focus or narrow angle. In a confined situation a wide angle lens is necessary to embrace the whole subject. A medium focus is useful for general subjects, and is the lens usually supplied with camera. A long focus lens is useful for distant shots. As an example of the special advantage of a long focus lens I have made these rough sketches of an imaginary bridge, the only point of view being the opposite side of a river. Fig. 4 would be the probable result with a wide angle lens, Fig. 5 with a narrow angle or long focus, and the medium focus would come about half way between. Lenses are provided with *stops* for increasing the detail

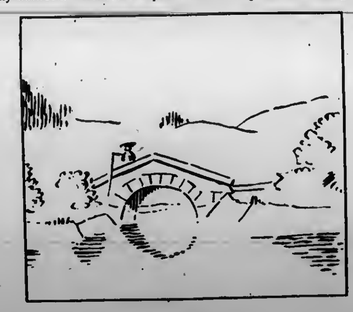

FIG 5.

in the resulting photo ; the smaller the aperture of stop the sharper the detail ; and just here I might mention that *as far as the lens is concerned*, the length of exposure depends upon the size of the stop ; the larger the stop, the more light passes through and the shorter is the required exposure. The amount of light passing through different size stops *varies directly as the area of each stop*. For example I will take two stops an ½" (Fig. 6), and an ⅛" (Fig. 7). Now as the area of one circle is to another as the squares of their diameters, by finding the areas you get the proportionate exposure. And as a circle ½" diam. is 1/16 the area of one ½" diam., Fig. 7 stop will require 16 times the exposure of Fig. 6, because only 1/16 the amount of

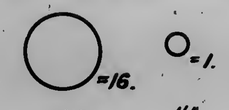

FIG 6. FIG 7.

intensity of light will pass through. So when you have by experiment found out the time of exposure for one stop, you can easily arrive at all the others. Stops are of three makes: 1st, "the diaphragm," which is inserted in a slit in top of lens mount, and objectionable because they are loose and liable to be lost ; 2nd, "the revolving," which is attached to lens mount ; and 3rd, "the Iris," also attached, and by which any size stop desired can be formed. Besides the aperture of stop, the time of exposure depends upon two other factors, the quality of the light and also the rapidity of the dry plate.

For instantaneous work, that is when a shutter is used, it is necessary first to have a bright day, second, an open view with few dark shadows, and third, the largest stop of lens should be used and should be in diameter not less than 1/10 the focus of the lens—that is, if the distance from lens to plate is 5 inches, the stop should be at least ½" diameter. As for shutters, I will not touch on them now ; their name is legion, they are all sorts, sizes and prices, and I should not advise a beginner to get one to start off on, as instantaneous shots are much more difficult to develop than ordinary time exposures, because they require rapid, or very sensitive dry plates, and the quicker the plate the more care and experience is required in development.

The next part is the tripod. This should be strong, light, and rigid when set up, should have sharp points at foot to grip a floor with, and should be easily and quickly set up and down, and make a neat and compact affair when folded up. All such inventions as walking stick tripods and folding tripods, warranted to go in vest pocket, are to be avoided ; get something that can stand a gust of wind, which the beforementioned contrivances assuredly cannot do.

The dry plate holders are of two kinds—the "book holder," so called because it opens like a book ; and the solid, both of which you can see here to-night ; the solid is the best kind, being the most convenient. It is very necessary that they should be well made and thoroughly light tight ; and even then it is best not to expose them more than necessary to direct sunlight. It is best to have three slides ; each slide holds two plates, which are placed back to back, and have a thin sheet of opaque card between them to prevent exposure having effect on the back plate.

The prepared glass plates on which the image is taken are called dry plates, to distinguish from the old style of wet plate used in the early days of photography. In those days it was necessary when taking views, for the photographer to take a kit with him comprising a fully equipped dark room, with chemicals complete, right on the ground where the view was ; he had to prepare and sensitize his glass plate right on the spot, and make the exposure and develop the negative while the plate was still wet, and as this had to be done in all weathers, you will recognize what a "snap" the modern amateur photographer has, especially with his aggressive little hand camera loaded for a dozen or more shots at all the out-of-the-way and novel bits his restless optic seizes on.

The dry plates are coated on one side with a mixture called "the emulsion," and composed chiefly of gelatine and nitrate of silver ; the sensitiveness of plate is due to the nitrate of silver, the gelatine being chiefly a vehicle to carry the silver salt.

Dry plates are made of different degrees of sensitiveness or rapidity, the rapid being used as I have mentioned, for instantaneous work. It is decidedly best for beginners to work at first on slow plates, as there is a greater amount of latitude ; the exposure and development has not to be brought down to the fine point that the rapid ones require.

Although the manufacture and subsequent working with dry plates is so well understood, it is a curious and remarkable fact that the true chemical effect the action of the light has on the dry plate has not yet been discovered.

The remaining necessity for exposure is a focussing cloth to throw over head and camera, so that image on ground glass can be seen while focussing. The best article is of rubber cloth, which would also come in handy for covering camera in case of a shower of rain.

I now come to the second head, viz., *Development*. For development, you will require scales and weights, chemicals, a glass graduated measure, two stoppered bottles, two trays, a dark room with red lamp, and plenty of clean water. Before lighting the red lamp, solutions of the necessary chemicals must be prepared. These are pyrogallic acid and an alkali—generally carbonate of soda—and cold solutions of these are poured into the glass bottles. The pyrogallic acid is the developer proper, but if used by itself would be tediously slow, therefore an alkali is used to quicken the appearance of the image, and this alkali is called the "*accelerator*." You will also require to prepare a solution of hyposulphite of soda, which can be at once poured into one of the trays.

You now light the red lamp and see that no stray rays of white light find their way into dark room. On taking dry plate out of plate holder, it will be found on examination to have the same appearance as it had when placed in holder before exposure ; no trace of image can be seen. The plate is laid in tray, gelatine side up, and a small quantity of the two solutions is then mixed, just enough to cover plate, and is poured evenly over. The tray is gently rocked and the image begins gradually to appear, the sky or any other high lights showing at first as dark patches. Development is finished when image begins to show through to back of plate, which must be watched. The plate is then rinsed in water to wash off the developer and is then laid in fixing solution. Up to this part the plate, although showing every detail of picture, has retained its semi-opaque creamy appearance, but on placing in fixing bath this is dissolved out in about ten minutes, leaving the negative perfectly clear and transparent in the shadows, and when it is so fixed it must be taken out and given a good washing in cold water. The plate after washing is then laid to drain and dry, and when perfectly dry your negative is complete. The development of a plate is by far the most fascinating part of photography, and the charm of watching a picture lull of rich detail, slowly appear on the surface is quite sufficient to account for the enthusiasm that all amateur photographers feel for this their hobby.

The third heading is the *Printing*. For this you will require a printing frame, sensitive paper and chemicals. The negative is placed in frame, film

side up; the sensitive paper is placed on negative prepared side down; this can be done in an ordinary room, but not too close to a window; the sensitive paper has nothing like the sensitiveness of the dry plates. The frame is then placed in a good light, not direct sunlight. It can be taken indoors and examined from time to time, and printing should be carried on until the print is a few shades darker than the finished photo is required, as it loses depth in toning. When a sufficient quantity are printed it is necessary to tone them and then fix the image. Toning can be done by gas or lamp light; and you will require to mix up a solution of chloride of gold with sufficient alkali to neutralize the acidity of the gold. The prints are first washed to get rid of the free silver, which leaves them of a brick red color, and then placed in toning bath. It is best to use crockery ware for the necessary dishes for toning. I myself generally make a raid on the kitchen for my supply. In a few minutes after placing in toning bath the prints will change to a more pleasing tone, and can be taken out at any stage desired, or can be left in until the tone is almost a black. Prints are then rinsed and placed in fixing bath for 15 minutes; they are then given a good washing and left to dry. All that then remains is to trim them and mount with starch.

There are several methods of printing, each of which has its own particular beauty and suitability for special subjects; you will find on table a few specimens of the different methods.

The many by-ways of photography, such as "lantern slide making," "enlarging," "stereoscopic work" and other branches, all have their devoted followers and enthusiasts, and all help to raise photography to that summit of true art which it richly deserves. When a camerist has perfected himself in the purely mechanical part of the processes, he then stays his hand at reckless firing off at everything he sees. He finds himself almost unconsciously developing a taste for something better than a merely good technical photograph, and by this means his mind is expanded; he sees beauties in nature he would otherwise have passed unheeded, and he finds himself the possessor of bits of composition that all help as an inspiration and make him feel that life is very well worth living.

Coming now to that very practical and important part, the cost, I think I can give you a full price list of the various articles required. A camera like mine, called the "Instantograph," will cost $15 complete with camera, lens, shutter, plate holder and tripod. The dry plates cost 45 cents a dozen; scales and weights, 75 cents; 2 trays, 20 cents each; a 2 oz. glass measure, 30 cents; 2 stoppered bottles, 12 cents each; printing frame, 20 cents. The cost of chemicals and paper is purely nominal; I have worked out the cost of six prints finished complete, and it comes to an average of 10 cents for 6 prints, which includes everything except cost of dry plates. All these prices are for ¼ plate size.

I think I have now exhausted my subject, and I sincerely hope you are not in the same condition. I would say in conclusion that if there are any present who think of becoming amateur photographers, both our worthy president and myself are entirely at your service for any advice or help that you may require.

THE POTSDAM RED SANDSTONE CO.

THE quarries of this company are situated at Potsdam, N. Y., and their selling yards for the Canadian trade at Prescott, Ont. The Parliament Buildings at Ottawa, are constructed of this stone. Prof. J. S. Newberry, of the Columbia College School of Mines., made an examination of the Potsdam quarries in 1860, and in his report says:

As I have said, I was surprised to find in the different quarries of this Company so many varieties of color in the stone. In the west quarries, the typical "Red Potsdam," either plain or banded, prevails. On their southern tracts are out-crops of homogeneous and monochrome, chocolate colored stone, in heavy ledges, which will yield blocks of any desired size. while in their quarries on the east side are exposed about fifty feet of rather massive layers, seperated by a band of fifteen feet of foundation or bridge stone. The upper and lower bands composing the fifty feet referred to, are mainly of light colored homogeneous stone, to which I was a stranger before visiting the quarries. This is of a reddish cream color, very uniform in tint and pleasing to the eye. It comes out in layers from two to six feet in thickness, and splits with ease and certainty in any direction. With the choclate colored stone, to which reference has been made, it may be combined with fine effect, one variety being used for trimming to the other, as corner stones, door and window caps, porches, etc., or associated as block stones in plain walls. This cream colored variety works with comparative ease, and may be wrought into mouldings and ornaments, much more cheaply than the harder varieties, which will be best used when hammer dressed, a style of treatment to which every phase of the stone will lend itself, as it breaks true and even under hammer.

The different tracts of land controlled by this Company comprise about two hundred acres.

The long-established hardware firm of Aikenhead & Crambie, Toronto, has been succeeded by the Aikenhead Hardware Co. The business will be continued as before in the premises at No. 60 Adelaide street east, which will, however, be altered in such a way as will best serve the requirements of the business. A specialty will be made of builders' hardware. Mr. Thos. E. Aikenhead is the manager of the new company.

SHAVINGS.

Messrs. Carroll & Vick, Toronto, are preparing specimens of brown Credit Valley stone for exhibition at the World's Fair. The block will be 3 feet high by 2½ on the side, and will be richly carved with foliage and the name of the stone, also the Ontario coat of arms.

The Toronto Chemical Smelting Company, of Port Colborne, Ont., is about to manufacture hard, black glass building and paving brick. The material is obtained as a result of the use of a new patent process of reducing and refining nickel from the ores, and would, unless utilized in this manner, be an absolute waste. It is claimed for these brick that they will be extremely hard and durable, and especially adapted for paving purposes. One of the streets in Port Colborne will shortly be paved with them.

Messrs. Pilkington Bros., the well known English glass manufacturers, have recently opened a Canadian agency in Montreal, and are protesting against the action of the Canadian Customs authorities in imposing a higher import duty on their material than is charged Belgian glass of the same quality. The matter is under consideration by the Controller of Customs. The effect of the discrimination against the English house is said to amount to about $100 in duty for every 1000 boxes or 100 feet of glass sold.

Mr. Wm. Jones, who was the original contractor for the erection of the Freehold Loan Company's new building, Toronto, but was dismissed from the work by the architect, Mr. E. J. Lennox, on the ground that satisfactory progress was not being made, has caused writs to be issued against the Freehold Loan for $20,000 for work done, also for $20,000 damages for breach of the contract; against Mr. Lennox for $20,000 for trespass, and against Mr. Snarr, to whom the completion of the contract was entrusted, for $5,000 for taking possession of the plaintiff's property.

CANADIAN ARCHITECT AND BUILDER.

VOL. VI.—No. 11. TORONTO AND MONTREAL, CANADA, FEBRUARY, 1893. PRICE 20 CENTS $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),
PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.
C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
64 TEMPLE BUILDING, - MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

WM. J. HILL.
WM BOOTH.

JOHN L. PHILLIPS, Secretary.

WE have received many compliments from subscribers and advertisers upon the character of the New Year Number of the ARCHITECT AND BUILDER published last month, for which we return our sincere thanks.

SOME Toronto architects and contractors, acting upon the suggestion printed in these columns soon after the conflagration which destroyed the city of St. John's Nfld., have visited the colony, and secured a considerable amount of work. Canadian manufacturers are also supplying large quantities of materials, which are being employed in the rebuilding of the city.

REPRESENTATIVES of the Toronto Builders' Exchange recently waited upon the members of the Ontario Government and presented arguments in support of needed amendments to the Mechanics' Lien Act. It is to be hoped that at the coming session of the Legislature an effort will be made to simplify the Act and render more equitable its provisions.

THERE is reason to protest against the unfair treatment which is frequently accorded to non-resident contractors who, in response to public advertisements inviting tenders, submit bids for municipal works. A thoroughly responsible contractor of Hamilton recently sent in the lowest tender for the supply of certain iron pipe required by the city of Toronto, and was given the contract. Subsequently, we believe, a pretext was found for taking the work from him and giving it to a local firm. Since then a contract for paving has been awarded to a Toronto contractor by the Board of Works of Hamilton, and pressure is being brought to bear on behalf of local contractors with the object of depriving him of it. This is a most unjust way of doing business. Either let it be publicly understood that no outside contractor need expect to get the work, regardless of what may be his ability to perform it as satisfactorily and at less cost than local contractors, or else let each tender, by whomsoever submitted, be considered entirely on its merits. Circumstances should in most instances enable the local contractor to the work more cheaply than an outsider, but if notwithstanding this advantage, the estimate of the outsider should be the lowest, and his ability to carry out the work equally unquestionable, he most certainly should receive the contract.

THE question as to the best course to be pursued in the erection of the new city and county buildings in Toronto, has been under the serious consideration of the City Council and the architect for several weeks past. The Council have been advised by their solicitor that they are powerless under the terms of the contract to interfere in any way with the architect in any course of action which he may see fit to pursue. On the other hand the opinion is expressed that so long as the city authorities refrain from attempting to direct the architect's course, no responsibility will attach to the city for his conduct. The city's solicitor deems it improbable that the courts would in any event order that the present contractor for the work be entrusted with its completion, but that he should be otherwise compensated for any damages to which he may be found to be entitled. The Council at their last meeting adopted a resolution in which the opinion was expressed, that while fully protecting the interests of the city, the architect should at once take such steps as would insure the resumption of building operations at the earliest moment in the spring. The situation undoubtedly requires the most cautious procedure on the part of the architect in order to avoid the

possibility of expensive complications. Before the publication of our March number the Courts will probably be engaged on the evidence in the dispute between the architect and the contractor.

THE third annual convention of the Ontario Association of Architects, the proceedings of which *in extenso* are printed in this paper, was the most important that has tak n plaee since the time of organization. Questions of vital importance to the welwelfare and even to the existence of the Association called for consideration. One of the most important related to the dissatisfaction of the country members, as expressed in their petition to the Council, with the amount of the annual fees. In the petition referred to they pointed to the surplus of nearly $2,000 standing to the credit of the Association in the bank, as evidence that the fees were unnecessarily high. Another question of much importance was that concerning the action which should be taken to induce the Ontario Legislature to amend the Architects' Act by striking out the word "registered" which at present appears in the Act in conjunction with the word "architect." In an ably constructed opening address the President considered at length these and other matters affecting the Association, and suggested the manner in which he thought they should be dealt with. The comprehensive and reasonable views expressed in this address, coupled with the fact that all reports concerning matters to be brought before the convention were, for the first time, placed in the hands of members in printed form at the opening of the meeting, had, no doubt, much to do with the very full and intelligent discussions which followed, and with, as we believe, the wise conclusions arrived at. It is somewhat difficult to account for the fact that only a small proportion of those who petitioned for a reduction in the fees were present at the convention to take part in the consideration of the question which they had been the means of introducing. There is every reason to expect that the conclusion reached with regard to this matter, will prove to them satisfactory, but should it unfortunately be otherwise, they should have no difficulty in deciding that to their own neglect is due the blame. The fees as altered would seem to be as low as could be adopted without impairing the financial standing of the Association. Time will no doubt prove the wisdom of the decision to fix the fees at definite amounts for every year rather than allow them to fluctuate from year to year according to circumstances. As to the return which outside members may receive for the fees which they are called on to pay, the benefits to be derived from a liberal use of the Association Library should alone be considered worth the expenditure. The additions which the Council have been authorized to make to the Library will render it increasingly valuable, and members would do well to take advantage of it to a greater extent than formerly. The result of the steps which are being taken to secure the amendment of the Architects' Act in the particular already mentioned, will be awaited with no little anxiety, as upon it must largely depend the future success and usefulness of the organization. The members throughout the country should lose no time in endeavoring to enlist the support of their representatives in the Legislature on behalf of the amendment. The object sought can be most efficiently promoted by this method, and at least cost. The formation of Chapters in various parts of the province, as suggested by Mr. Gregg, would, if practicable, prove most beneficial, but the experience of those who have tried the experiment, throws doubt on the probabilities of success. It might be worth considering whether interest in the Association would not be promoted by sometimes holding the meetings elsewhere than in Toronto—as for example, in Ottawa, Hamilton or London. The printed result of the tests of Canadian building stones made last year at the School of Practical Science, Toronto, under the direction of the Association, as presented by Mr. Townsend, chairman of the committee entrusted with the oversight of the work. They form a valuable feature of the proceedings, and must prove of great assistance to architects and builders. It is to be hoped that additional specimens of native stones may be tested, and also that similar tests may be applied to the varieties of native woods and other materials which enter into architectural and engineering work, in order that exactness of knowledge might characterize their use. A retrospective view of what the Association has already accomplished, despite the disadvantages under which it has had to labor, and consideration of the many directions in which it might do valuable service on behalf of the profession and the public in the future, should assure to it at this critical period in its history the wisest counsel and earnest support of every architect in the Province.

ILLUSTRATIONS.

DESIGN FOR AN $800 COTTAGE.

This cottage is designed to face south, and comprises a kitchen and a living room (or parlor and dining room combined) together with three bedrooms. It is purposed to be constructed of frame on a stone foundation, and to have excavation under kitchen for cellar. External walls and roof are intended to be shingled, and the interior to be lathed and plastered throughout.

DESIGN FOR CONCERT HALL AND COLLEGE OF MUSIC.—G. F. STALKER, ARCHITECT, OTTAWA, ONT.

ST. BASIL'S NOVITIATE, TORONTO.—POST & HOLMES, ARCHITECTS, TORONTO.

C. A. & B. COMPETITION FOR A CITY HOUSE—DESIGN BY "ETUDIANT" (MR. J. EUGENE PAYETTE, MONTREAL) AWARDED SECOND POSITION.

TORONTO BUILDERS' EXCHANGE.

The annual meeting of the Builders' Exchange, of Toronto, took place on Wednesday, January 18th. The following were present:

Messrs. Wm Hill, Curtis & Rowe, J. Lister Nicholls, Wm. Booth, James Crang, D. Williams, Jno. Aldridge, Wm. Pears, Wm. Britnell, Jno. Brodigan, M. Murphy, Jno. Hanrahan, Wm. Park, Wickett Bros., J. Isaac, Bayliss & McCurdy, Jno. Price, Isaac Price, Geo. W. Gore, H. Martin, Benj. Brick, R. Robertson, Geo. Moir, Mr. Richardson, W. J. Burroughes, R. Hewitt, Oakley & Holmes, Mr. Fox, Geo. Wright, F. Lockwood, R. Chalkley, Wm. Wood, Jas. Priestley, Jas. Pears, A. E. Smythe, Jno. Maloney, M. Vokes, Jno. M. Gander, W. R. Simmons, Robt. Whittam, Jos. Brown, E. Farquhar, T. W. Self, Samuel Young and John Barnard.

The President, Wm. J. Hill, took the chair at 3 o'clock. The Treasurer's report showed the finances to be in a very satisfactory condition. The report of the Secretary showed a membership of 146, divided as follows: Brick Manufacturers' Section, 25 members; Masons' and Builders' Section, 68 members; Cut Stone Section, 14 members. The remaining members comprise carpenters, plasterers, plumbers, stone merchants and dealers in lumber, sewer pipes and cement, etc., who have not yet organized into sections. The Board of Directors had held 36 meetings during the year, and the Finance Committee met nine times. Attention was called to the fact that the by-laws had been amended so that, when necessary, disputes between members and the expense of litigation might be avoided.

The election of officers was then proceeded with. The name of Wm. J. Hill was proposed for re-election as President, but Mr. Hill stated that his duties in the City Council would prevent him giving the time necessary for the performance of the duties of the position.

The following officers were duly elected: Wm. Pears, President; Geo. Moir, 1st Vice-President; Geo. Oakley, 2nd Vice-President; David Williams, Treasurer; Wm. J. Hill, James Crang, Wm. Park, Jno. Aldridge, Wm. Booth, Directors.

The Board of Directors will further be increased by one representative from each Section of the Exchange. Wm. J. Hill then vacated the chair, and Mr. Wm. Pears upon taking his seat as President, thanked the Exchange for the honor conferred on him, and asked for the assistance of all the members in carrying forward the work of the Exchange.

A very hearty vote of thanks was tendered Mr. Hill, the retiring President, for the very able manner in which he had performed his duties. Mr. Hill responded in suitable terms, and the meeting then adjourned.

LEGAL DECISIONS.

ROBERT A. BALLOCH v. FRANKLIN H. HOOPER.—Where one borrows money to erect houses upon land belonging to him and conveys the land before the houses are finished to another, and the latter borrows other moneys to finish the houses from the same company who loaned to the former, all which moneys are secured by deeds of trust, in an action by the first owner against the second and the company which loaned the money for an accounting, &c., such company is entitled to a lien upon the property to secure the payment of all moneys advanced by it, says the Supreme Court of the United States.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

Of the 34,455 houses standing this year in Montreal, 25,774 are built of brick, 5,482 of stone, and 3,118 of wood.

Mr. John J. Macdonald, one of the most prominent railroad contractors in Canada, died at the St. Lawrence Hall hotel, in this city, on the 12th inst. Mr. Macdonald was of late years a partner in the well-known firm of Manning, Macdonald, McLaren & Co., who built Section B. of the C. P. railroad on the north shore of Lake Superior, a most difficult piece of work. Mr. Macdonald was highly esteemed in business and social circles.

A board of arbitrators awarded $16,308 damages to the Trustees of Calvary Congregational Church, against the Atlantic and Northwest Railroad Co., on account of loss alleged to have been sustained in depreciation in the value of their property by reason of the running of trains close to their property since the railroad obtained its entrance to the Windsor street depot. The Superior Court has reduced the award to $1,367, refusing to allow damages except for the right of which the church had been deprived to build over a lane, and for deprivation of light and air. An appeal has been taken by the trustees from this judgment, and the decision is expected to be given on the 28th inst.

AT the last monthly meeting of the resident members of the Province of Quebec Association of Architects, Mr. Joseph Veuve gave an address on "Archæology in its Relation to Architecture." The benefits accruing from the study of archæology, in freeing the student of architecture from narrowness of ideas, were dwelt upon. The paper was a most interesting one, and evoked considerable discussion. Mr. Taylor promised on his own behalf and that of other members of the Association to deliver lectures before the students during the winter, provided those for whose benefit the proposal was made, would show by their attendance that they were desirous of being thus instructed. The bill concerning laborers, mechanics and contractors, which is to be presented at the next session of the Legislature, was also discussed, and the opinion of the Association was that laborers and mechanics were quite sufficiently protected under the present code, and that no further protection should be furnished, as it would lead to fraud and would encourage the growth of an irresponsible class of contractors.

AN IMPORTANT POINT AFFECTING BUILDERS AND ARCHITECTS IN THE PROVINCE OF QUEBEC.

An action was brought against the Royal Electric Co. to recover $325 for rebuilding a chimney which had been constructed a short time previous by plaintiff, and had fallen. The plaintiff alleged and proved that the defect in the construction was owing to the defective plan furnished him by defendant's architect. The Court held, however, that this did not exonerate the plaintiff from responsibility, that the law made him jointly and severally liable with the architect for the loss, and dismissed his action. This rule of responsibility appears to be hard, but it has been long settled on principles of public policy, and is or should be known to every builder, who must contract therefore with reference to it. If any one does not wish to assume the full responsibility imposed by the law he should have an express provision inserted in his contract to exclude or modify his responsibility. The decision was based upon the following Articles of the Civil Code, which are declaratory of the law of the Province of Quebec:—Art. 1688—If a building perish in whole or in part, within ten years, from a defect in the construction, or even from the unfavorable nature of the ground, the architect superintending the work and the builder are jointly and severally liable for the loss. Art. 1689.—If in the case stated in the last preceding Article, the architect do not superintend the work, he is liable only for the loss which is occasioned by defect or error in the plan furnished by him. After ten years architects and contractors are discharged from the warranty of the work they have directed or done.

USEFUL HINTS.

Granite is the lowest rock in the earth's crust. It is the bed rock of the world. It shows no evidence of animal or vegetable life. It is from two to ten inches as thick as the united thickness of all other rocks. It is the parent rock from which all other rocks have been either directly or indirectly derived.

A Pacific coast journal says: It is a well known fact among car and bridge builders that Douglas fir is stronger than white oak and will last fully as long. Tests bear out the assertion. A recent test was made at the Northern Pacific car shops, Tacoma, with a piece of fir and one of white oak. Both pieces were of the same length, width and thickness. By laying the two pieces with the end on a piece of iron and putting weights in the centre, it was found that the white oak broke, while the fir sustained one-quarter more weight without showing signs of breaking. In a test for end breaking the white oak showed its superiority on account of its fine, close grain. Therefore, where fir can be used flat, it is stronger than oak; but where the timbers are to be used in the shape of pile drivers or battering-rams, oak or other fine-grained woods are best.

TO DARKEN OAK.—Oak for decorative wood work is produced by fumigating the material with ammoniacal vapor, which effectively produces the dark coloring so much desired. In accomplishing this, the method consists in placing the material to be darkened in an approximately air-tight room in which no light enters; or for small work a packing box will suffice, the joints or cracks to be well pasted over with paper. In this room or receptacle for depositing the furniture or other article is placed a flat porcelain or earthen vessel filled with ammonia, the vessel containing the liquid being, of course, set on the ground or floor, that the fumes or vapor may strike to advantage the articles to be darkened; if the apartment is large, two or more vessels containing ammonia may be employed and allowed to remain until the desired effect is secured. The ammonia does not touch the oak, but the gas that proceeds from it acts in a peculiar manner upon the tannic acid contained in oak, browning it so deeply that a shaving or two may actually be taken off without removing the color. The depth of shade depends upon the quantity of ammonia used and the duration of exposure.

BAY WINDOWS AND ORIELS.

The distinction between a bay and an oriel is as follows: By the former is understood a projecting window, or rather a projection pierced with window opening in its entire width and rising immediately from the ground, whether it be confined to the lower part of the building or carried up through one or more stories above the ground floor; by the latter a bay which does not descend to the ground, but is suspended over the face of the wall beneath it. Oriel accordingly corresponds with the German terms *Erker-fenster* and *Bhor-fenster*, which are almost the only ones of similar import in any foreign language. This absence of a name for it is accounted for by the thing itself being scarcely known in the architecture of other countries, and in our own it occurs only in our Domestic Gothic or Tudor, such form of window being very rare indeed in ecclesiastical structures. In our Domestic, which also comprises collegiate architecture it is, a beautiful and valuable feature, and one which admits of very great diversity of design and also imparts much variety and liveliness of effect to a building, more especially if there be ground bays likewise, the two kinds of projection both harmonizing and contrasting with each other. Internally there is no distinction between bays and oriels inasmuch as both the one and the other form a recess whose sides are filled with windows. But greater variety of plan occurs in oriels than in bays, which are usually more spacious as to breadth and of shallower proportions as to depth; they are also either rectangular in plan, or form three sides of an octagon, whether a regular one or not, whereas curved forms are of frequent occurrence in the plans of oriels and are occasionally combined with straight ones. Yet as similar plans do occur in bays no real distinction can be found upon such accident of design.—*Architect.*

BORED MOLDING.

Hardwood, a Chicago lumber trade paper, suggests that hardwood moldings would be much more popular if they were bored for nailing, similar to the way hardwood flooring is now bored by many first-class mills. It says: A great deal of stained softwood molding is used, simply because it is so easy to fasten in place, when hardwood would be preferred and would be used but for the extra work required in using it, much hand boring and the most careful nailing being necessary to prevent splitting. Maple makes a beautiful molding in connection with certain kinds of finish, but it is almost impossible to fasten it without boring to prevent splitting. This is especially true of the cleanest and whitest of soft or white maple. Much oak, both white and red, also requires boring, while chestnut, which is very desirable from its lightness and close resemblance to oak, should always be bored for every nail. Black walnut will always pay for the extra trouble even of the expensive hand boring, and such cheap and common woods as gum and basswood will be found to pay for boring, as would Norway and yellow pine. A competent machinist declares that a machine for boring can be attached to the sticker or regular molding planer, so that the stock will require no extra handling, and that can be made adjustable to any width of molding or any sized bit or any length of space between holes, varying from the finest cabinet stock to the ordinary house trim or picture molding. House trimmers and cabinetmakers are ready to welcome the first bored stock offered. They know and realize the benefit such a thing would be to them. Who will be the first to advertise molding with the catching alliterative phrase of the flooring men, "bored, butted and bundled?"

A sketch for a Canadian cottage, by Mr. Ernest Willby, late of Toronto, appeared in the London *Building News* of Nov. 18th.

The medal offered by the *Painters' Magazine* to the pupil of the painting class of the New York Trades Schools has been awarded to William H. Leacock, of Westport, Ont.

TESTS OF BUILDING STONES.

WE present below the result of the tests of building stones conducted last year at the School of Science, Toronto, under the direction of the Ontario Association of Architects, together with the report thereon of the Committee appointed to conduct the tests. This Committee was composed of the following members of the O. A. A.: Messrs. S. H. Townsend, W. G. Storm, D. B. Dick, E. Burke and S. G. Curry, Mr. Townsend being the Chairman. The Committee was assisted by Professors Galbraith and Coleman, Messrs. Wright and Rosebrugh, of the School of Science. We publish also several illustrations, taken from photographs, showing the appearance of some of the most perfect specimens at point of fracture.

TORONTO, JANUARY 31st, 1893.

To the President and Council of the Ontario Association of Architects:

GENTLEMEN:—

I have the honor on behalf of your Committee to lay before you the results of the tests of building stones, lately conducted at the School of Practical Science.

The stone to be tested was first sawn into cubes, then set in plaster of Paris in a steel frame made for the purpose, and brought to perfectly parallel faces by rubbing.

In placing the specimens in the machines care has been taken that the pressure was always applied at right angles to the natural or quarry bed of the stone.

Specimens of all the stones tested have been preserved, and a complete set of these, together with all data connected with the tests, including in most cases photographs of the stones broken, will be kept at the School of Practical Science and at the office of the Association, for the benefit of those wishing further details.

Very truly yours,

S. H. TOWNSEND,
Chairman of Com.

No. 1.

Connecticut Brown Sandstone from the Middlesex Quarry Co., Portland, Connecticut. Supplied by Messrs. Brown & Love.

SANDSTONE, medium grained, purplish brown, consists of quartz grains, with some grains of felspar, and many scales of white mica. Very slight effervescence with acid.

Specimen.	Section under Pressure.	Height.	Crushing Load.	Crushing Stress per Sq. In.	Average Crushing Stress per Sq. Inch.
	Ins.	Ins.	Pds.	Pds.	Pds.
A	3 1/8 x 3	2 7/8	89,000	9,493	
B	3 1/8 x 3	2 7/8	92,000	9,813	
C	2 7/8 x 3 1/8	2 7/8	78,000	8,858	
D	2 7/8 x 3	2 7/8	64,000	7,420	8,896

No. 2.

Stone from the "MONO" Quarry, owned by the Owen Sound Stone Co., and situated two and a half miles north of Orangeville, Ont.

SANDSTONE, very fine grained, pale greenish grey. Effervesces slightly with acid, showing presence of carbonates. The stone is in beds of from one to four feet thick and can be got out in large sizes. It has to be teamed to Orangeville Station.

Specimen.	Section under Pressure.	Height.	Crushing Load.	Crushing Stress per Sq. In.	Average Crushing Stress per Sq. Inch.
	Ins.	Ins.	Pds.	Pds.	Pds.
A	3 1/8 x 3	2 1/4	139,600	15,194	
B	3 1/8 x 3	2 1/4	130,000	13,866	
C	2 1/8 x 3	2 1/4	114,000	13,155	
D	3 x 3	2 1/4	131,000	14,555	14,192

No. 3.

Credit Forks Brown Stone, from Carroll & Vick's No. 2 Quarry, Credit Forks, Ont.

SANDSTONE, fine grained, reddish brown. Contains quartz, and a little felspar and mica. The stone is in beds of four feet and under, and can be handled in pieces up to five tons. Quarry 300 yards from Railway.

Specimen.	Section under Pressure.	Height	Crushing Load.	Crushing Stress per Sq. In.	Average Crushing Stress per Square Inch.
	Ins.	Ins.	Pds.	Pds.	Pds.
A	.....	.....	.....	.....	
B	2 7/8 x 3	2 7/8	131,000	15,188	
C	2 1/8 x 3	2 7/8	130,000	14 751	
D	3 x 3	2 7/8	133,000	14,777	14,905

No. 4.

Stone from the St. John's Quarries, Longford Mills, owned by Messrs. A. McPherson & Co.

LIMESTONE, compact, with some fissures, pale grey, effervesces strongly with acid. The stone is in beds of from 6 inches to 2 feet, and may be loaded upon cars in quarry.

Specimen.	Section under Pressure.	Height.	Crushing Load.	Crushing Stress per Sq. In.	Average Crushing Stress per Square Inch.
	Ins.	Ins.	Pds.	Pds.	Pds.
A	3 x 3	2 7/8	200,000	22,222

C	.....	.....	.....	.....	
D	3 x 3	2 7/8	175,000	19,444	21,352

No. 5.

Stone from the Hope Bay Quarries, owned by Messrs. Wm. Hooson & Sons, Plumper Pass, B.C.

SANDSTONE, medium grained, with some larger grains, bluish grey. Contains quartz, with some felspar and mica, and probably hornblende. Effervesces slightly with acid. The stone is in parallel beds of from two to ten feet, and can be loaded on scows or light draught vessels at the Quarry, which is situated on the North shore of Pender Island, about midway between Victoria, Vancouver, and New Westminster.

Specimen.	Section under Pressure	Height	Crushing Load.	Crushing Stress per Sq. Inch.	Average Crushing Stress per Square Inch.
	Ins.	Ins.	Pds.	Pds.	Pds.

THIRD ANNUAL CONVENTION ONTARIO ASSOCIATION OF ARCHITECTS.

THE third annual convention of the Ontario Association of Architects was held pursuant to announcement, on Tuesday and Wednesday, the 7th and 8th inst.

FIRST DAY.

The chair was taken by the President, Mr. S. G. Curry, at 3 p. m.

The following members were present:

S. G. Curry, Toronto; K. Arnoldi, Ottawa; W. A. Edwards, Hamilton: J. E. Belchei, Peterboro': F. H. Herbert, Toronto: E. L. Rastrick, Hamilton; H. C. McBride, London; Jos. W. Power, Kingston; M. B. Aylesworth, Toronto; J. A. Ellis, Toronto Junction; A. F. Wickson, Toronto; John Gemmell, Toronto; Mark Hall, Toronto; Geo. Gouinlock, Toronto; F. S. Baker, Toronto; W. A. Langton, Toronto; Fred. Henry, London; W. L. Symons, Toronto; Frank Darling, Toronto; Edmund Burke, Toronto; W. R. Gregg, Toronto; A. H. Gregg, Toronto; John Kay, Paris; J. W. Kenny, Collingwood; Frank Helliwell, Toronto; S. H. Townsend, Toronto; H. J. Webster, Toronto: R. J. E. Edwards, Toronto; N. B. Dick, Toronto; T. J. Ruttley, Chatham: H. Simpson, Toronto; Commander Law, Toronto; H. B. Gordon, Toronto.

The minutes of the last meeting having been read by the Registrar, the President read his address, as follows:

PRESIDENT'S ADDRESS.

This is the third annual meeting of the Ontario Association of Architects, and I believe that it will be considered in the future as having been weighted with most important issues. At this meeting, many questions of vital interest must come up for discussion and settlement. The life of the Association depends upon the action which the members may take during this convention. We have nearly reached the critical point in our existence which many of us have seen coming from the beginning, and which if safely passed will carry the Association forward to a period of great usefulness.

This Association is working under an Act of the Provincial Legislature which, to all intents and purposes gives us neither benefits nor privileges, while it imposes on us the duty of educating the future members of the profession, that the public may be benefitted in the future. The Act is of so little practical benefit that it was only after considerable discussion and consideration that it was determined to try to carry out its provisions. This decision was arrived at only when it was pointed out that we could expect to obtain all that we desired in our first effort, and that there was reasonable hope that we should eventually succeed in having the Act changed so that it would really serve the purpose for which it was passed. As you will see by referring to the report of the Council, an effort was made at the last session of the Legislature to have the Act amended. We found the opposition from the members of the Legislature against legislation having the slightest appearance of giving special privileges to any profession or organization so strong, that it was worse than useless to press it at that time. Moreover, we were in hopes that by waiting one year we should be enabled to cite the State of New York as having passed an Act giving the profession in that State greater privileges than we were seeking. The Act passed both bodies of the New York Legislature, but was vetoed by Governor Flower on representations made to him by five architects residing in the city of New York. That the Act was approved by the representatives of the people proves progress, but it does not materially assist us in procuring any changes in our Act. However, another effort on the part of the architects of New York State will probably give them the Act which they so nearly succeeded in obtaining, and which should benefit the people of the State to an extent to which they have little or no conception.

The Legislature of British Columbia failed by just one vote in making the profession in that province a close corporation. If the architects had asked for no more than we are now asking for, they would have secured the required legislation with little or no opposition.

Our Council has been pursuing the course which they think most likely to lead to eventual success, that is, to try and carry out the educational features of the Act and thereby show that we are in earnest in our desire to improve the professional standing of our members.

The public have no sympathy with us in any efforts which we may make to improve our own condition unless they can see some direct benefit to themselves. We must therefore take up the measures in which the public are directly interested before we attempt to improve our condition as a profession in those respects in which we are more directly interested as practising architects.

The difficulties in the way of obtaining amended legislation can only be properly understood by those upon whom the duty has been imposed of getting the desired legislation. At this point I would like to draw the attention of the members of the Association who reside outside the cities to one of our difficulties in obtaining such changes in the Act as nearly all of us believe to be necessary to its successful working; and that is, that while it is possible to convince the city members that there is danger to life and health from the incompetency of an architect, simply because they live in large centres of population and can see the result of such incompetency, it is not so impossible to convince the average country members that any danger exists. The fact that those who bring the question before him are city architects is sufficient to place him in opposition, as he immediately conceives that they have some ulterior object in view which is opposed to the interests of the architect or the builder in his locality.

If each of our members residing in the smaller cities, towns and villages should explain our position to his representative in the legislature, showing him that the amendments to the Act which we seek would not only benefit the city architects but all the architects in the Province, while at the same time benefitting the public, nearly all opposition would be removed. I do not think it unreasonable that the Council should expect some assistance from the individual members of the Association; but I regret to say that very little assistance has been given; the majority of the members seeming to think that the Council required no assistance. There are even a few who apparently take delight in placing stumbling blocks in the way, if the course of the Council does not meet with their entire approval, no matter how much or how little they may know of the inward condition of affairs. There is not the slightest objection to any member having opinions of his own, but he should advocate them at the proper time and in the proper place. If his suggestions are accepted by the majority, he should be more than satisfied, but if not, he should be willing to abide by the decision of his fellow-members and loyally aid in carrying out that decision until he is able to win over a majority by fair and open criticism. No good is gained by personal opposition but much injury is done and as a result all suffer—the obstructionist along with those to whom he has placed himself in opposition.

The Council interviewed the Government two weeks ago, and have reason to believe that we may succeed in having the Act amended by the striking out of the word "Registered" where it occurs in the Act if each member will do his duty in the premises. The Council ask that every member will do his utmost to aid them in obtaining the amended legislation. Let no one believe that his assistance is of no importance. Every member of the Legislature who is convinced that the changes which we suggest in the Act will be of benefit to the public, is just one opponent gained over to our side to give us his assistance.

The first examination of the Association was held last April in the examination hall of the School of Practical Science. The report of the Council gives a clear statement of the number of students who came up for examination and of the number who passed. A supplemental examination was held in September which is also referred to in the report. The Association is to be congratulated on the success of its first examination, as a large number of those who should have taken the examinations presented themselves.

I am aware that many of the members look upon the educating and examining of the students as a work the expense of which should not be borne by the Association. Some of them hold that the student should pay sufficient fees to clear expenses—that since they receive the direct benefit they should be made to meet the cost. This argument may be a very good one on general principles, but it is impracticable. If the student is asked to pay high fees on presenting himself for examinations, he will decline to take them, and the educational work of the Association will be blocked. No doubt it would be urged that if the students should not present themselves they would be the principal sufferers and that the Association could wait until they recognized the value of the examination; but how long could the Association wait under the present condition of affairs? It could wait, it is true, but while it would be waiting there would be formed a body of architects outside its influence and opposed to its principles. It is evident that until we get greater power, we must be content to bear the expense of the examinations or give them up altogether, for the students will not assist to any appreciable extent. As a matter of fact, there were a number of students who refused to present themselves for examination last April stating that they could not see that they would be placed in any better position as architects by taking the examinations. This feeling on the part of the students is more likely to increase than diminish until the Association is in a position to offer greater inducements to bring the students up for examination of their own free will or is enabled to force their compliance.

Before dropping this question I should like to state that in my opinion every member is interested more or less in the better education of the students. A student who studies systematically in order to pass an examination will be of more service while under indenture than one who is idle and indifferent. The draughtsman who has acquired his training under the above conditions will be able to render more valuable services than the man who has picked up his knowledge without method. The architect who has students, or who employs draughtsmen should derive some benefit from their greater efficiency. There is another way in which he will derive a benefit, and that is in the fact that the better the man is educated for his work the more likely he is to insist upon receiving proper and suitable compensation, thus reducing competition as to the amount of commission to be received by the architect. It is true, however, that while the competition as to the amount of commission to be paid may be reduced, the competition against which the less proficient architects will have to work will be greater owing to the better and more efficient training of their competitors. But still, I think that even under such conditions the position of the older men will be much improved through the greater respect which the public will have for the profession as a whole, when the younger men are forced to properly prepare themselves for their work. But the strongest argument which I can urge in favor of the Association carrying on this work of education, is that it is about the only way in which we, as members of the profession can show that we have, not only our own interests, but those of the public at heart. We certainly cannot be expected to be given privileges, which, so far as anyone outside of the profession can discover, will only benefit ourselves. We cannot expect to be assisted in building up a close profession or trades union. Whatever privileges we may obtain can only be secured in return for work accomplished or to be accomplished through us for the benefit of the general public. I believe that few would complain if the Act gave us only adequate assistance in doing the work which it has imposed upon us. Where the trouble lies, is in the fact that we are expected to do educational work without the power to do it effectively. We are asked to do work persuasively where we should be empowered to enforce compliance with the educational provisions of the Act. Under these conditions some have become discouraged and desire to give up the struggle. But I strongly urge that before accepting defeat, every effort should be made to win. Much has been done, and it may be that now when everything appears dark and disheartening we are near the period when success is at hand. Whatever we do, do not let us entirely give up the work which we have undertaken until it is absolutely hopeless to struggle longer.

You will also see by the report that we have a very useful though small library. Some of the students and a few of the members have profited by it; but a careful study of the report will show that the library is not patronized as it would be if all were anxious for instruction. The library, it is true, is not of very much benefit to the members as yet, except in so far as it enables them to supply their students with standard architectural works suitable to their attainments. Still, at the same time, there are books in the library which would be very useful to all of us if we would but read them. It was the intention of the Council, when we established the library, that as soon as such books as were absolutely necessary to the advancement of the students had been acquired, to purchase by degrees, as the finances of the Association would allow, the more expensive standard works which are not within the means of the average architect. Such books, under our method of sending them to members, would be of very great value, but they can only be acquired by years of effort on the part of the Association. Owing to the condition of the Association, the Council have not, during the past year bought any more books than they found absolutely necessary.

The Council is able to, at last, present the report of the committee appointed to test the stones used in this Province in the erection of the more important buildings. This report has been long delayed and some complaints have been made that it was not published months ago. But I should like to point out that the preparing of the report has almost entirely devolved upon the chairman of the committee, Mr. Townsend. It has taken up a large amount of his time, as he had all the computations and tabulations to make, as the other members of the committee only assisted in making the tests, which occupied several days. You can hardly expect a man to completely neglect his own private work to do that of the Association. I for one consider that all the members of the Association are greatly indebted to Mr. Townsend for the work he has done, at so much sacrifice of time. We as an Association must not expect that those who do our work without remuneration should do it as if they were paid officials. It is largely a work of love on the part of such members and it should be accepted as such by us, with proper acknowledgement of our indebtedness. This report is a most valuable one and should be useful to each and every member of the Association.

During the past year the Council sent a deputation to Ottawa to interview the Government, relative to the fact that plans were admitted into this country practically duty free. It was in many respects a disagreeable duty which the Council had to perform, but as many of our members were complaining of the unjust competition with which they had to contend, the Council determined to make an effort to mend matters.

We as a section of the community paying our due proportion of the duties levied by the Dominion Government under the National Policy, upon the necessaries and luxuries required by us in living comfortably, have every whit as much right to the consideration of the Government, as the manufacturers or other bodies of the community. I am pleased to inform you that the Manufacturers' Association recognized this point and gave us such assistance as they could, in presenting our case before the Hon. Ministers, Messrs. Foster and Bowell. While as you may see by the report, we were promised something—indefinite it is true—we have received nothing so far as we can discover.

The Council were also instructed by the last convention to determine what could be done to protect an architect's design from being used by a second party without compensation. You will see by the very thorough report of Messrs. Arnoldi and Ewart that under the present copyright law, nothing can be done to remedy the evil, and it is more than hopeless to have the matter dealt with in a way that would be satisfactory to us and to the public at the same time.

At the request of the British Columbia Institute of Architects, the Government of British Columbia requested the Council of the Ontario Association to name experts to decide the competition for the new Legislative and Departmental buildings proposed to be erected in that province. The Council selected Mr. Andrew Taylor, P.R.I.B.A., R.C.A., of Montreal, and myself to act as the experts, and the appointment was immediately confirmed by the Government of British Columbia. The fact that the Government of British Columbia asked our assistance on this most important occasion, shows that they had confidence in us as an Association of Architects. We can therefore congratulate ourselves that our efforts to improve our professional standing have received recognition, while at the same time we were enabled to render some small assistance to a sister Association.

The Council arranged during the year that the Registrar should keep a list of draughtsmen who desired employment. Very little advantage was taken of this arrangement, owing, probably, to the fact that, as there was so little work in progress during the summer, the draughtsmen deemed it useless to register their names. However, it was the means of several draughtsmen obtaining positions during the year.

You are no doubt aware that the Association has a regular indenture for students, which was approved of at the last convention.

The "Conditions of Competition" which were approved by the Association have not been printed as the Council deemed it unnecessary to incur that expense until an occasion should arise for their use.

The Association is now in possession of a seal, which was designed by Mr. Edmund Burke.

I had the pleasure last September of attending the annual meeting of the Quebec Association, and cannot speak too highly of their hospitality, which, no doubt, was extended to me as your representative. I believe it would be of great benefit to both Associations if each would send at least two representatives to take part in the conventional proceedings of the sister Association. They should have every privilege extended to them except the power of voting. By such means we would be brought closer together and each would have a better knowledge of the work carried on by the other Association.

I also had an invitation to attend the second annual meeting of the Southern Chapter of the A. I. A. which met in Birmingham, Alabama, on the 12th of January last. I was unable to accept the invitation owing to lack of time and the distance to be travelled.

The extending of invitations by the representatives of one Association to those of another, to be present at the annual conventions, is a very friendly and effective way of showing our interest in each other's work. This spirit of mutual interest should be cultivated by the accepting of such invitations on all occasions when possible.

I now wish to refer to a petition for a reduction in the annual fees, which was received by the Council during the year. This petition was sent in so very late in the year that it was impossible for the Council to take any action on the lines suggested, even though they had deemed it desirable. The annual fees had been fixed by the first Council and practically approved by the Association, as no objection had been raised by any member until the petition had been sent in. By referring to the by-laws of the Association and Council, you will find that the entrance fee was placed at $15.00, which also included the fee for the balance of the first year. The regular annual fee was placed at $15.00 for Toronto members and $10.00 for members residing in other portions of the province. Such being the case, it was unwise to circulate a petition in the middle of the year and long after the fees were due. The effect of circulating the petition was to delay the payment of fees in very many cases, and to induce some not to pay them at all.

Such questions as this, should be brought up at the annual meetings, where there is an opportunity for a full and ample explanation and intelligent discussion and settlement. Do not misunderstand me, I am not opposed to criticism, either fair or unfair, of the management or of any interest of the Association, so long as the criticism is made honestly and when and where it can be dealt with at once and effectively; but I am opposed to any action on the part of anyone which tends to unsettle the minds of the members during the year, when it is utterly impossible for the Council to take any action, especially when such action, if taken, would be a radical change in the policy of the Association.

One of the objects of holding these annual meetings is to allow the members to bring up any questions which they may deem of importance, for discussion and settlement; and if any member considers that the fees are too high, it is his place to bring the question before this convention and to have it settled by the full membership of the Association. The Council does not desire to control the affairs of the Association except for its benefit, and to the entire satisfaction of its members; and when their policy has met with no opposition during the past year it is only natural to believe that it will meet with approval in the succeeding year. No radical change in the management of this Association should take place on the suggestion of the Council or of any number of the members of the Association, unless such change has been discussed and approved by the members in convention.

I will now refer directly to the substance of the petition. The surplus which was quoted as a reason for the lowering of the fees was not really as large as it was stated to be, as all the accounts against the Association were not in at the time the books were closed. The surplus has been acquired from the registration fees and not from dues over and above the running expenses. The running expenses of the Association now rather exceed the income than otherwise, and if our membership should decrease, as no doubt it will, unless we obtain a change in our Act, there will be annual deficits to be met out of the surplus. The Council have from the first assumed that the membership of the Association would diminish each year. Many of the members joined, under the impression that it would benefit them in some direct way, since the Association was formed under a special Act of Parliament; they have since found that our position is not what they supposed and are now allowing their membership to lapse.

The reduction in membership has naturally reduced our receipts, and we are therefore in a position in which we must not only consider the minimum amount at which our annual fees should be fixed, but also in what respects the work of the Association can be reduced with the least possible injury.

Some will hold that by reducing our fees we may retain our full membership, but the trouble is that if we reduce our fees to a point sufficiently low to retain our membership, we shall receive a very small total income; whereas if we hold our fees at the present amounts we shall have a larger total income on a very much reduced membership. With a small membership our numbers will consist of men who are enthusiastic in the work of the Association, and I believe greater progress will be made.

We have now reached a condition where careful study of our position, and a far sighted policy is required to carry us safely into port. It will also require on the part of each member a willingness to do all that he possibly can, to tide the Association over present difficulties. It is for this meeting to take such action as it may deem best in the interests of the Association.

To aid in the solution of our difficulties, I would suggest that the fees payable to the Association be changed to the following amounts, graded to represent the interests of the different classes of members, viz.:—Members residing in Toronto of five years standing and over, or those who are members of firms of five years standing and over, $15.00; members residing in Toronto of less than five years standing, $10.00; members residing in other cities in the province, of five years standing and over, or who are members of firms of five years standing and over, $10.00; other members in these cities $5.00; members in towns, villages, etc., $5.00; members in civil service or in the employment of corporations but who do not practice *privately*, $5.00; travelling members or those not residing in the province, $5.00; draughtsmen who have passed the final examinations, $5.00. If the fees were thus graded, no member would have any reasonable ground of complaint, since the members who derive most benefit from the Association would pay the highest fees.

It is not advisable to lower the fees to too great an extent, as we should look forward to establishing a reading room containing all the published professional papers and a library of the most important and valuable standard architectural works. The members in Toronto could use the reading room with much advantage to themselves, while it would be at the service of the country members for the transaction of business whenever they were in the city. The library would save members buying expensive books for which they have comparatively little use.

During the year some of the members have complained that they were not receiving anything in return for their fees. If they meant they were not receiving any monetary return they were probably right. This Association was not formed on the basis of giving values for fees in a direct and tangible form, but rather in an indirect and possibly intangible form. But I think that anyone who is impartial and reasonable will be able to discover that he has received some benefit even now, and that there is every hope of his receiving greater benefit in the near future, if the members of this Association are true to it and themselves. Do those who join the many fraternal societies hope to receive any monetary return for their fees? I know of none except possibly those who use these societies for their own personal advantage. The greater number of our members, I am sure, joined this Association, not so much for the good that it would do them, as for the good that they might do in aiding the Association to accomplish a much needed and highly desirable work. This work is the raising of our profession to the position to which it is justly entitled in the vanguard of the other professions. And if this position should be attained, will anyone here state that each and every one will not then have received full value for what little he may have paid out in fees to this Association? But are there not some returns even now which are of some little value? Is the library of no benefit? It certainly is not to those who do not use it, but would it not be of great benefit to very many who do not use it and who also complain of receiving nothing in return for their fees? Is the report on the crushing and other qualities of our building stones of no value? Are not the papers which have been read at these conventions and afterwards published of benefit? Are not many of these subjects on which reports have been made of importance to our members? Has not the drawing up of a student's indenture and a set of competition conditions, been some good accomplished?

Gentlemen, I have no hesitation in stating that if all of our members were loyal to the Association, and upheld the Council in its action, much more good would be accomplished to the advantage of us all. But where we have personal opposition which even goes so far as to strive to bring about serious defections, we cannot hope to accomplish over much. Do all our members refuse to take students who do not register? And do they not retain in their offices both students and draughtsmen who will not comply with the requirements made by the Council and approved by the Association? Some have even gone so far as to abet such opposition on the part of students and draughtsmen. Is such conduct what one should expect from members of this or any other Association? Is not the work of the Council and this Association sufficiently difficult one without it being made still more so, by petty opposition? Let those who do not approve of the management of the Association, come here and enter their protests in a manly way, and if possible gain the support of their fellow-members for any suggestion they have to make, which in their opinion will be beneficial.

I have devoted this address entirely to considering the position and business affairs of this Association. Our position at the present time is a serious one, and it behooves us to carefully consider our affairs, that we may go forward if possible along the road which will carry us to the goal of our aims and desires.

I have spoken plainly, but I hope without offence to anyone. I have no desire to hurt or offend any member, but I think that plain dealing with difficult questions at a serious period is the only way in which we can acquire a firm foothold on a sound foundation. My anxiety to see this Association secure in its position is my excuse for stating my opinions plainly, and I only hope that others will do the same and then we shall know exactly where and how we stand.

I regret that it is my sad duty to refer to the serious loss which our Association sustained in the sudden and lamented death of Mr. W. G. Storm, R. C. A., the first President of this Association. Little we thought one short year ago, when Mr. Storm took his position on the platform in the room below this one, as President of the Association, that he would ere another year had passed, have departed from this world and his work, to that other world of which we know so little and to which we are all travelling. Of his skill as an architect I will not speak, but will leave the buildings which he erected during his busy life, to speak for me, since you are as capable as I am of estimating his professional attainments through them. For the advancement of this Association he worked earnestly and at considerable sacrifice of his material interests. He did not work in hope of any personal gain or benefit, but out of love for his profession. Many times, he stated that it was more than likely that he would have passed away, long before

the Association would be enabled to do very much for the advancement of the profession. But he cherished the hope that the students of the present day, who will be the architects of the future, would derive some benefits from his labours. He did not live for himself alone, but for the good of his fellow-men and especially for those engaged in his chosen profession. He set us, one and all, an example which we could follow with much advantage to this Association and ourselves.

Many of us hoped, when he retired last year from the Presidency, that we should see him again in his old position as President of this Association, but it has, however, been ordered otherwise. But while we will never again see him in body, we may keep him in remembrance by taking him for our example, and carrying through the work which he supported so loyally. Let not his name nor his works pass out of our remembrance.

The President then called upon the Acting Treasurer to read the Treasurer's report.

Mr. Burke, who stated that he had been requested by the Treasurer, Mr. Dick, when that gentleman was leaving for the old country a few weeks ago, to take charge of the books and report, read the report as follows:

THE TREASURER IN ACCOUNT WITH THE ONTARIO ASSOCIATION OF ARCHITECTS.

1892	*Receipts.*		
Jan. 1	To balance in bank	$2,163 15	
Feb. 19	To cash from Registrar	32 45	
July 26	" " " receipts 1st February to 30th June	901 65	
Sept. 16	To cash from Registrar, receipts for July	96 00	
Sept. 16	" " " " Aug.	12 00	
Oct. 18	" " " " Sept.	10 00

Dec. 31	By balance in bank	2,285 35	
			$3,438 16

We have examined the books, vouchers, etc., of the Association, and certify that the above is a correct statement thereof.

(Signed) HENRY LANGLEY, W. L. SYMONS } Auditors.

The Registrar then read the following report:

REPORT OF THE REGISTRAR AND LIBRARIAN FOR 1893.

Members.

The roll of membership of the Association on January 1st, 1892, contained 73 resident members and 74 non-resident members, in all 147. Of these, 11 resident members and 7 non-resident members, in all 18 members, were in arrears with their fee for the portion of the year 1891 between August 7th, the anniversary of the date of registration, and December 31st, the close of the financial year of the Association. Thus, though the Council decided to assume the continued membership of all and continue all names on the roll, the number of members in good standing at the close of the year 1891 was only 62 resident members and 67 non-resident members, 129 in all. Of these 2 resident members and 1 non-resident member have since paid these arrears. The remaining 15 form part of the number of members to be subtracted, as not in good standing, from the roll of membership at the close of the year 1892.

The roll at the close of the year 1892 numbered 119, there having been 1 registration as architect of a student who had passed the final examination, and 1 architect in practice at the time of the passing of the Act admitted to registration, under sec. 22, sub-sec. 2, of the Act. Of these 104 paid their fees during 1892, and 11 sent in their resignation, leaving 34 who have not paid their fee, but have not signified their intention of withdrawing from the Association.

Since the beginning of the year there have been 2 more membership fees paid and 2 registrations as architect on the part of students, so that the roll of members in good standing at the time of publication of this report numbers 108, consisting of 44 resident members, 59 non-resident members, and 5 members not practising in Ontario. This latter class of members was created by the Council to meet the needs of members who found it necessary during the present depression of business to seek employment elsewhere, but who did not wish to give up their membership of the Association.

Students.

There were 96 students on the roll at the beginning of 1892, classified according to the examination required of them, as follows:—

First intermediate	4
Second intermediate	30
Final	62

36 students came up for examination in April, classified as follows:—

First intermediate	4
Second intermediate	12
Final	20

Of these the Board of Examiners recommended and the Council passed:

First intermediate	2
Second intermediate	3
Final	13

11 were conditioned for a supplementary examination in September.

9 came up for examination, viz.:—

First intermediate	2
Second intermediate	4
Final	3

Of these were passed:—

First intermediate	2
Second intermediate	4
Final	2

In all there were 15 students who passed the final examination, and are entitled to register. Of these only 2 have registered.

The new form of indenture, approved by the last Convention, came into use as soon after as it could be lithographed, and there are now 9 students articled under this form.

The register of draughtsmen out of work, which is open at the office of the Registrar, and of which notice was given at the last Convention, and in the CANADIAN ARCHITECT by the publication of the Registrar's report, has been practically unused, 4 students only and 1 architect, who was in search of a superintendent's place, having entered their names. I think I may say that it was in consequence of this application that the architect is at present prosperously employed.

Proceedings of the Council.

The Council have held three meetings; the first on February 4th, the second on May 5th, and the third on October 18th.

Following instructions from the Convention, the Council appointed a Committee to investigate the possibility of obtaining copyright for architectural plans. The report of the Committee has been printed, and is in the hands of the members of the Association.

The Convention had further instructed the Council to procure, if possible, amendment to the Act of Incorporation, by striking out the word "Registered" before the word "Architect." Application to this end was made to the Minister of Education, who replied that it would not be prudent to attempt any amendment in the current session.

A deputation in conjunction with the Province of Quebec Association of Architects, went to Ottawa with a memorial to the Minister of Customs. The memorial and report of the deputation have been printed, and are in the hands of the members of the Association.

A design has been adopted for the seal of the Association. It has been cut and is now in use.

Subsequent to the May meeting of the Council a memorial signed by 49 non-resident members of the Association was received by the Registrar. The President called a meeting of the Toronto members of the Council, who instructed the Registrar to send out the circular letter to members of the Council, which has been printed and is in the hands of the members of the Association. The non-resident members of the Council wrote in reply their opinion as to the right course to pursue. The Council agreed that the fee should remain as fixed by by-law until the next Convention. Pursuant to this decision the Registrar sent out the circular dated July 18th, to all non-resident members, which has been appended to the printed copy of the circular letter to the members of the Council concerning the protest.

The register not being fully signed at the close of the last Convention, it was first sent to the larger cities to procure signatures of the members residing in them. Afterward, a slip with a headline, "Signature for Register of Ontario Association of Architects,' was sent to all members whose signature had not been received. Many signatures were thus returned, and have been pasted in the register; but there still remain 25 members who have paid all fees, but have not signed the register. Of the signatures received, there are 13 of the members who are in arrears for the fee of 1892, and 2 of members who have paid no fee since registration.

A letter was received in October from the Commissioner of Lands and Works, of British Columbia, asking the Council of our Association to select two architects to act with the Department of Lands and Works in examining the plans sent in for competition of designs for new Government Buildings, to be erected at Victoria. The Council selected Mr. Curry, our President, and Mr. A. T. Taylor, of Montreal. The selection was accepted by the Commissioner of Lands and Works, and these gentlemen acted as experts in the preliminary competition which was decided in November.

A Committee of the Council waited in January upon the Ontario Government, and presented a memorial concerning the amendment of the Ontario Architects' Act. The Government expressed themselves favorably towards the proposed amendment, and steps are being taken to have a bill introduced at the coming session of the Legislature.

The Library.

The Library contains the following works:—

Bayles. "House Drainage and Water Supply."
Baillairgé. "Geometrie and Toise Tables."
"Clef du Tableau Stereometrique."
"The Stereometrican."
Papers read before the Royal Society of Canada and the Quebec Literary and Historical Society.
Baldwin. "Steam Heating for Buildings."
Billings. "Ventilation and Heating," 2 copies.
Bloxam. "The Principles of Gothic Ecclesiastical Architecture," 2 vols.
Brandon. "Analysis of Gothick Architecture," 2 vols.
Chambers. "Civil Architecture."
Clark. "Building Superintendence."
Cotterill & Slade. "Lessons in Applied Mechanics."
D'Avesnes Prisse. "La Decoration Arabe."
Fergusson. "History of Architecture," 2 vols.
Gerhard. "Drainage and Sewerage of Dwellings."
Gibbons. "Law of Contracts."
Gruner. "Specimens of Ornamental Art with Descriptive Text by Emil Braun."
Gwilt. "Encyclopedia of Architecture."
Hendrick's Architect's and Builders' Guide and Contractors' Directory of America.
Jenkins & Raymond. "The Architects' Legal Handbook."
Kidder. "Architects' & Builders' Pocket Book."
Macassey & Strahan. "The Law Relating to Civil Engineers, Architects and Contractors, 4 copies.
Mitchell. "Building Construction."
Osborne. "Notes on the Art of House Planning."
Paley. "Gothic Moldings."
Parker. "A. B. C. of Gothic Architecture."

Viollet le Duc. "Lectures on Architecture," 2 vols.
"The Habitations of Man in all Ages."
Wightwick. "Hints to Young Architects."
Wright. "Architectural Perspective."

The sum of $235.30 has been spent in the purchase of books; $184.05 in 1891, and $51.25 in 1892.

The Library was opened for lending on October 1st, 1891. Since that time there have been 203 books borrowed; 31 in 1891, 157 in 1892, and 15 in January of the present year. Of the 203 borrowings, 31 were by architects, and 172 by students.

On motion of Mr. Burke, seconded by Mr. Belcher, the report of the Treasurer was adopted.

On motion by Mr. Gemmell, seconded by Mr. Edwards, the report of the Registrar and Librarian was adopted.

The Convention then proceeded to the consideration of "Business arising out of the minutes."

DISCUSSION.

Mr. Edwards called attention to the desirability of having the "Conditions of Competition" printed and circulated among the members of the Association, so that they might be in a position at any time when called upon to hand those Conditions to persons seeking competition. He would, if necessary, move that the Conditions be printed, though it was merely a suggestion on his part, as he recognized that it was the work of the Council.

The President replied that although the action to be taken was a matter for the Council, it was within the province of the members assembled in convention to instruct the Council to take any steps thought advisable.

Mr. Edwards: Then I will move that the "Conditions of Competition" be printed and circulated among the members of the Association.

Mr. Helliwell, in seconding Mr. Edwards' motion, stated that there was much force in that gentleman's arguments as to the importance of having the Conditions of Competition printed, not merely for the reason given, but also that the matter might be kept before members themselves. While speaking of printing, he desired to bear testimony to the great advantage of having the various reports printed and placed in the hands of members attending the Convention, as had been done on the present occasion, as it enabled them to follow and discuss the matters in question more intelligently than would otherwise be the case. He thought the slight expenditure this incurred was a very wise one.

Mr. Wickson inquired if another benefit arising from the printing of the Conditions would not be that members who were approached and asked to submit competitive sketches would find it a very easy and concise method of replying, to forward the printed Conditions to such applicants, stating that under those Conditions only, they submitted competitive drawings.

Mr. Gordon thought the proposed action of printing and circulating the Conditions would have a valuable educational effect.

Mr. Burke believed that not only the public, but some of the members, would derive an educational benefit from the perusal of the Conditions, if printed and circulated as proposed.

Mr. Edwards expressed his gratification at finding his views so generally endorsed, and his ideas elaborated upon by the members present. He thought what had been said covered the ground admirably.

The President: I certainly think it would be a decided advantage to have the Conditions of Competition printed as has been suggested. I may say the only reason they have not been printed is, that the Council, having received a petition to reduce the fees, felt that for the remainder of the year it would be well to conduct the affairs of the Association as economically as possible, and meanwhile to ascertain what was really the feeling of the Association with regard to expenditure. It is, of course, impossible to go on making expenditures unless we have an income. As far as the surplus is concerned, it will not be difficult to dispose of that, but at the same time, I think we should make our income and our expenditure as nearly equal as we can.

The President then put Mr. Edwards' motion to the convention.

Mr. Edwards suggested that sufficient copies be printed to enable a few copies to be in the hands of every member.

Mr. Simpson thought it would be well to have printed on the same sheet the scale of architects' fees.

The President said that there was no tariff adopted by the Association.

The motion was then carried.

THE LIBRARY.

Mr. Aylesworth, referring to the advisability of reducing expenditure, said he had been struck by the idea that the money expended on the library might not perhaps be well applied. For his own part, while aware of its existence, he did not know where it was, or of what it consisted, and he wondered to what extent it was known of by other members. If it was not of any particular advantage, was it well to continue to expend money on it in the meantime?

The President: The meaning of the last speaker, to me, is not very plain. The announcement of the library's existence has been placed in the hands of every member, with information as to the conditions, etc., on which books can be obtained. While perhaps not in constant use for purposes of reference, the library certainly has been made use of in that way to some extent. The only trouble is that it is in need of improvement to be of advantage to members, its advantages at present being almost entirely confined to students preparing for examinations. What I, for one, would advocate is the application of a portion of our surplus to the purchase of books of greater value to members of the Association. I may say that every member of the Association, no matter where he resides, can have any book sent to him, and is allowed to keep it for a certain length of time, the only obligation cast upon him being to pay the postage and preserve the book in proper condition.

Mr. Aylesworth: What I meant to say was, that so far I have not looked up the library, and I understood from others that they were in the same position; and I did not know whether it had been of service to anyone. There are a number of valuable books both in the School of Practical Science and in the Public Library, but how many of them are being used? If they are not used, our small library would be less made use of, and if it is not of practical benefit, why should we continue to expend money on it? Of course, if it is being made use of, well and good, and if additions to it will enhance its value, it is merely a question of how useful it will be.

Mr. Gordon: If I may criticize in any way the financial aspect of this matter, I would say that I cannot see the wisdom of having $2,000 odd lying in the bank, when a portion of it might be much better utilized in procuring for the library works which might be looked at by architects with advantage. While it is true Toronto members have access to the Public Library and other collections, certainly those residing in the country should be very anxious for the improvement of the library, and I may say, speaking of my firm, that we have occasionally made use of the Association Library, and I think the city members should also be anxious to increase its efficiency. I think we should instruct the Council for the coming year to expend more money upon this library, and, if a motion were in order, or necessary, I would move that the Association, recognizing the desirability of increasing the efficiency of the library, recommends the Council to make such judicious expenditure of the moneys in their hands as may to them seem advisable to that end.

Mr. N. B. Dick: I do not quite agree with what Mr. Gordon says about increasing the expenditure. I am not one of the forty-nine kickers against paying fees, but it is evident from the results of high fees that we are diminishing our membership, and I think we ought to move in the direction of reducing expenses, for that seems to be the trouble with many of the outside members, and, indeed, many in our own city. It seems to me that the expenses of the Association have been unnecessarily large. I think something may be done in the way of reducing the expenses of meetings of the Council. I hardly see the necessity of bringing in members from a distance to consult on matters of minor importance, and paying their railway and travelling expenses. I think most members of the Association will be satisfied to appoint men in Toronto, or in some other city. Then I would like to ask what the expenses are in connection with students? There is an item of, I think, $250 in connection with the examination. Are examiners paid for their services?

The President: Yes.

Mr. Dick: Don't you think members of this Association ought to take sufficient interest in its affairs to be willing to give their necessary time gratuitously? Let us cut down expenses in that way. (Hear, hear.) I know, for my own part, though I fear my usefulness would not be great, that I should be very glad to do anything I could without remuneration. While I am not sufficiently conversant with the matter to enter into its minutiæ, I believe it would be possible to reduce our expenses by one half, and thus not only retain our present membership, but add to it, instead of having it decrease from year to year.

The Registrar: I think I had better explain to Mr. Dick that the amount of labor involved in connection with the examinations is very great, and means a great deal more than a few days' attendance here. There was at first the arranging of the curriculum, then setting papers and attendance during the examination, afterwards the labor of examining the papers. The fee of each examiner was $25, for which some of them examined on four or five subjects. That sum is entirely out of proportion to the fees paid to an examiner in the School of Practical Science or the University, and, as far as being any adequate return for the services rendered in connection with the examinations, might almost as well be dispensed with, but I think it would be most unreasonable to expect four or five members to do all this work for the whole Association for nothing, and also, if the examiners are paid, it establishes better the business character of the examinations and the responsibility of the examiners to the Association. Some other way out of the difficulty must be found. A proper way would be to increase the charge to students, but that is a matter for future consideration.

Mr. Edwards called the attention of the chairman to the fact that proceedings were becoming somewhat irregular, there being two subjects under discussion at one time, the reduction of fees and the augmentation, or otherwise, of the library.

The President, while admitting the discussion to be slightly irregular, thought it would do no harm, as the matters under

consideration were intimately related, to spend a little time in that way.

Mr. Gregg suggested that, as the next report was that of the Committee appointed to make tests of building stone in use in Canada, it would be well to hear that report and then devote the remaining time to the discussion of the state of the Association.

The President concurring,

Mr. Thompson moved that the report be taken as read. Carried.

Mr. Gregg moved the reception and adoption of the report, together with a vote of thanks to Mr. Townsend and the other members who assisted in its preparation.

The motion being seconded by Mr. Belcher, was carried.

THE STATE OF THE ASSOCIATION.

Mr. Edwards, referring to the proposed changes in the Act, spoken of in the President's address, expressed a desire for a little more information on the subject. He thought it would be a matter of congratulation if they were as successful in the near future as the President's address seemed to contemplate. He wished to say that the Council had not, as stated in the address, been laboring unaided, for he felt sure that outside members had been bringing to bear what influence they could towards the desired end. At the same time, would it not cause a good deal of kicking throughout the country if the change were effected? He thought it well not to be too sanguine in regard to this matter, but if the President had any reasons for the hope he had expressed, which could be made public, the members would no doubt be glad to hear them.

The President: With regard to the change and amendments, there is really no deviation from the policy adopted in the beginning. We sought to procure an Act conferring upon qualified members of the profession the right to use the word "architect." The Government, or some one connected with the Government, inserted in the Act the word "registered," which had the effect of destroying its force, and which we desire to have removed from it. The sooner that word is removed, the sooner will the opposition we encounter be decreased. If it is allowed to remain five years, there will be so many more outsiders opposed to it, or who will have to come in, because, practically, when that word is knocked out, we will have to admit every man who at that time is working at the profession; we could not at the end of that time interfere with the men who had started up in practice, and had made use of the word architect. That would be interfering with a vested right, which is something we could not do.

Mr. Edwards: Then anyone commencing business now as a practising architect can join the Association, and all we have done to the contrary is of no effect. In other words, we just place them where we ourselves stood at the time of the formation of the Association; they just come in as we did on organization, without passing any examination?

The President: Of course, I am only speaking of what I think myself. I think it would be unwise for us to adopt any other course, or to ask the Government to do anything else; it would only stir up opposition.

Mr. Aylesworth: I think this is a very important point. It is the first time it has been raised, and I think it would be well if all the members present would make themselves acquainted with that phase of the question, and, of course, it should also be early explained to the Government, that no one practising as an architect would be interfered with, even if they should not come in for several years. Of course, we did not contemplate this at first, but time has passed now, and probably more time will pass, so it will be well to keep in view this fact, that everyone now practising will have the same right he would have had a year or two ago. I think the matter should be thoroughly discussed and understood, and I think if the matter were presented to the Government in that light, it might have the effect of hurrying matters up.

The President: It has been placed before the Government in that light.

Mr. Gregg: It should be a matter of paramount importance with the Association to push this through, for until that word "registered" is struck out we will have accomplished practically nothing. With that object in view, I think it would be well for outside members to use their influence with members of the Legislature in their districts, so that when the matter comes before the House they will be properly acquainted with the nature of it.

Mr. Burke: The point with regard to members outside cannot be too strongly emphasized. Members outside of Toronto can approach thirty or forty members of the Legislature where the Association in Toronto can only approach three or four. I think, therefore, that our success in securing this amendment rests largely with the country members, for if they can favorably influence thirty or forty members of the Legislature the thing will go through without any trouble.

Mr. Gordon suggested sending to each member of the Legislature a printed statement of the argument in favor of striking out the word "registered." He thought if this was done it would make the work easier for members of the Association who approached them regarding the change.

The President said that a plain statement of the facts had been prepared for the purpose of forwarding to members of the Association, but no attempt had been made at any argument in it; that had been left to those who would approach the members of the Legislature, who, being acquainted with them, would be in a better position to judge of the best standpoint from which to present the argument. He feared a printed argument might possibly give rise to some misapprehension.

Mr. Helliwell thought the work of interviewing members of the Legislature could be better carried out by a Committee specially appointed for that purpose, as what was everybody's business often proved to be nobody's business. He would move the formation of such a committee.

The President replied that such a Committee already existed, in the Council of the Association, but it was better the work should be done by individual members, residents in the districts of the members of the Legislature it was desired to influence, and who, by reason of that fact, could appeal to them more forcibly than a stranger.

Mr. Belcher expressed the opinion that if properly approached the members would offer very little opposition. He had seen the members for both ridings of Peterboro', and also for the County of Victoria, and they had expressed themselves favorably. He thought if each individual member of the Association would put his shoulder to the wheel, very few could be found who would seriously oppose their wishes. He might add that both of the gentlemen he had spoken to were opposed to him in politics, but nevertheless the result had been as he stated.

Mr. Burke added that whereas in a city like Toronto many of the members of the Association were quite unacquainted with their representatives in the Legislature, in the smaller towns it was quite the reverse; probably they met these gentlemen almost every day, and on quite familiar terms. He thought, however, it would be well for a deputation from the Association to wait on the Attorney-General.

Mr. Helliwell explained that he had not meant that members of the Committee he suggested should personally wait on members of the Legislature, but rather that it should be their province to ascertain that they were seen by the members of the Association resident in their respective districts.

The President said the opposition which the Association might expect to encounter would arise from the prevalent feeling against close corporations, and instanced the opposition which was last year offered to the Surveyors' Bill. That opposition was engendered by want of knowledge and understanding of the object of the legislation sought, and that knowledge could be best imparted by the members of the Association who had opportunities of meeting with their representatives in the Legislature in their own districts.

Mr. Edwards reminded the Association that the opposition to close corporations was not confined to the Legislative Assembly, but was to be met with in the community generally. If the architects were influential in political circles, and could influence votes, it would go far to remove any opposition on the part of the legislators.

Mr. Helliwell disclaimed any desire to push his motion; he thought the publication of the discussion would serve to awaken members to the necessity of taking the requisite action. He would, under the circumstances withdraw his motion.

Mr. Gregg urged the necessity of reaching all the architects in the Province. If the proposed change would have the effect that had been stated on members of the profession outside of the Association it would be well they should know it, and they might assist in making a big push up the hill. He would suggest a petition, to be signed by all the architects in the Province.

Mr. Burke expressed approval of the last speaker's idea, and, as a member of the Council, he desired to see a large Committee entrusted with the matter, embodying, perhaps, the present Committee of the Council, and as many more members from the Association. He thought there could not be too many interested in the matter.

The President thought Mr. Gregg's suggestion a good one; but notwithstanding that course had been followed before, with reference to the desired change, the Government passed the Act without making the alteration. He thought he was correct in saying that members of the Association in default for fees still remained on the list of members.

The Registrar said nothing had been done towards removing such members' names, and they had been furnished with all matter connected with the present meeting.

Mr. Burke said if the request for the change were signed by every member and every ex-member of the Association, it would disarm all opposition.

Mr. Townsend expressed himself as being in favor of action in the line of Mr. Gregg's proposal; he would suggest that it be an instruction from this meeting to the Council to consider the advisability of obtaining such a petition.

Mr. Gregg stated that his object was that it might go out from this Convention that it was the desire of those present to secure the co-operation of all the members in the Province, whether they had attended the Convention or not, and whether they had paid their fees or not. He wished to preserve the friendship for the Association of every man who was practising in the Province, and to have it conveyed to them that the Association bore no ill-will against those who for various reasons might have dropped out.

Mr. Edwards believed that that line of conduct would defeat the objects of the Association. He advocated an adherence to the policy at first proposed, that each member should leave the Convention animated by a determination to influence those with whom he came in contact who were in a position to further the end desired. It was all very well, he thought, to be generous and magnanimous, but he disapproved of soliciting the co-operation of those who had separated themselves from the Association, many of whom would stay out under any circumstances; he thought the desired object could be attained by other means.

The Registrar said that the question of the proposed change would come before the Legislature at the approaching session. Members of the Government had already been seen by the Council, and had expressed themselves favorably towards the proposed change, although stating their inability to vouch for the opinion of the House on the subject. The matter was probably the most important with which the Convention had to deal, and the course which to him appeared most desirable, was that suggested by Mr. Burke, that the Committee of resident members should be requested to add to their number, so as to form a large Committee, and that the present discussion should form a portion of their instructions from the Association. If Mr. Burke saw fit to make the motion he would have pleasure in seconding it.

Mr. Burke accordingly moved that five members of the Association be added to the five members of the Council now constituting a Committee to interview the Legislature with the object of preparing for legislation in order to drop the word "registered" from the Act.

Mr. Gordon seconded the motion, and in doing so said that he was very loth that it should go out that they were prepared to surrender everything at the very outset. While fully appreciating the generosity and liberality of the views given utterance to by the President and the very nice way in which he had put things, and also believing that perhaps, in the end, those views might have to be adopted, he still believed that they ought not at the very beginning to be prepared to make that surrender. (Hear, hear.) He thought that in seeking to make confidants of the gentlemen who had elected to remain without the ranks of the Association, and, as it were, almost begging of them to come in, the dignity of the Association would be lowered without accomplishing the object which Mr. Gregg so earnestly desired. He gave that gentleman full credit for the object he had in view, viz., the disarming of opposition, but at the same time did not think it would be effected by such a policy. He thought the instructions of the Committee should be, first of all, to endeavor to get the word "registered" struck out of the Act without agreeing to any conditions, reserving assent to such conditions as a last resort, the supreme object being to get the objectionable word "registered" removed.

Mr. Aylesworth inquired if there was any number of the older members of the profession who were not members of the Association.

The Registrar replied, that, as far as could be gathered from letters he had received, all or at least all but a few of the older members of the profession were included in the Association.

Mr. Simpson asked if those who were practising as architects before the inception of the Act, and had failed to register, could, in the event of the word "registered" being struck out of the Act, be debarred from calling themselves architects?

The President thought they could not, unless the Legislature so provided.

Mr. Burke's motion was then put to the meeting, and carried.

COPYRIGHT AND CUSTOMS DUTIES.

The President called attention to the instructions given to the Council last year in regard to copyright, and asked if anyone was sufficiently interested to be desirous of making any remarks on the subject of customs dues.

Mr. Aylesworth remarked that he was so far interested in regard to the latter that he would like to hear how the proposition was received by the Minister of Customs.

It was explained to Mr. Aylesworth that the information with respect to the reception which the deputation met with was to be found printed in the report.

Mr. Gordon asked if it would not be well to express to the incoming Council the desirability of following up the question during the present year.

The President: It is a matter for the Association.

Mr. Gordon moved, seconded by Mr. Edwards, "That it is desirable that the matter of customs dues upon plans, etc., of foreign architects be again brought before the notice of the Canadian Government by the incoming Council." Carried.

GENERAL CONDITION OF THE ASSOCIATION.

The President: Some months ago the Council had sent out to each member of the Association a request that he would send in any suggestions which occurred to him regarding the better management or working of the Association. The Registrar will now read the replies to that request.

The Registrar having read the letters in question:—

Mr. Gordon said, that in view of the many feeling—with the emphasis on the last syllable—replies, the suggestion embodied in the address of the President as to grading fees was a good one. So far as he could see, the fees could not be very materially reduced without endangering the financial standing of the Association. In approving of the suggestion in question, he claimed credit for being disinterested, as he would still have to pay the larger amount. He thought the suggested plan of rating outside members from $10 down to $5 would remove the hardship under which, to judge from the communications received, some of them were laboring.

Mr. N. B. Dick said that it was evident there was much dissatisfaction among outside members and opposition to the fees now charged. He again advocated retrenchment in expenses. He would not like to see a motion passed to reduce the fees to any stipulated amount, but thought the matter should receive from the Council careful consideration, in view of the desirability of retaining in the Association as many members as possible, instead of having the membership reduced year by year.

Mr. Edwards, speaking of himself as a "country member," said he did not object to paying $15 as his membership fee, nor did he object to the reduction of the fee to $10 if it would help anyone to do right, but if the reduction was going to help men such as he knew of, who while too poor to pay the fees of the Association were rich enough to offer to give $1,000 to procure a $20,000 work of church alteration, he most decidedly objected. He was quite willing to help those who could not help themselves, but he entertained a decided aversion to helping others to take money out of his pocket.

Mr. Belcher expressed his satisfaction personally with the existing scale of fees. He was not aware that any of the so-called country architects were grumbling at the fees.

Mr. Aylesworth said that in order to test the feeling of the Convention he would move that the scale of fees suggested in the address of the President be adopted by the Association.

Mr. Burke thought that the fact that the older members had to pay the highest fee might in some instances be productive of hardship.

Mr. Darling said it was evident from the letters read that the matter called for consideration. The Association was yet in need of being fostered and nursed along, and while he did not express any opinion as to whether or not the fees were too high or otherwise, he advocated whatever would best do that. It would be a very great thing if they could stick together until the word "registered" had been got rid of. He did not think the question was one which could be disposed of off-hand at a meeting like the present, but that it would be better left to the Council.

Mr. Gregg thought one objection to the graded fees would be found in the extra labor entailed on the Registrar in keeping an account of the exact length of time members had been in business. He thought the best thing to be done was to drop the idea of augmenting the library, and some other things, draw on capital and reduce the fees for one year, hoping that with improving times, and the securing of the amendment, more interest would be manifested in the Association.

Mr. Edwards was opposed to asking Toronto members to pay any more than those outside.

The President explained that the scale of fees suggested in his address was prompted by information he had obtained from representatives of different sections to which the membership of the Association extended. He thought there was a great deal to be said in favor of only assessing members in proportion to the amount of benefit they derived from the Association. To men living in the smaller towns and villages, whose practice was limited, $10 was quite a serious item. He did not, however, think that the reduction would have the effect of keeping men in the Association—there would always be defaulters even if the fee was only one dollar. He thought that on the whole they might congratulate themselves that really very few members were retiring. On the formation of the Association a great many rushed in and registered, under the impression that by not doing so they would lose some right, and, not finding things just as they expected, after a time fell away. Yet there were 80 per cent. of those who had registered in good standing, so he thought the Association was really in very fair condition.

Mr. Burke suggested that a reduction of the fee by $5 be made all around.

The President said that would leave the Association without an income to meet necessary expenses.

Mr. Gregg thought a less reduction than that proposed by Mr. Burke would suffice, but thought the Association could afford some reduction.

Mr. Baker thought it was not so much a reduction of fees the non-resident members desired as something in the way of a return for them. He thought if meetings could be held three or four times a year, at which papers of interest could be read, and minutes published in pamphlet form, it would be regarded as some return for the fees.

Mr. Belcher agreed with the last speaker, that the periodical reading of interesting and instructive papers, and their distribution among the members who had not the opportunity of hearing them read, would stimulate interest in the Association. The members of the Society of Engineers received two reports a year, which contained a large amount of very valuable matter.

Mr. Gordon said there seemed to be some misapprehension existing in the minds of non-resident members as to the benefits derived by resident members from the Association. He in common with other architects in Toronto, belonged to three distinct organizations. As members of this Association, resident archi-

tects received no more benefits in the way of meetings or papers than were enjoyed by those living at a distance. But there was the Architects' Guild and the Architectural Club, each having fees of their own, and whose members received certain benefits. The only advantages enjoyed by city members of this Association over their brethren in the country, was that they had no railway fare to pay in coming to attend the annual meetings, and it was thought when the fees were fixed that a slight reduction in the fees of those outside might have the effect of equalizing matters in that respect.

Mr. Belcher said he had been under the impression that quarterly meetings were held by local members of the Association as was the case with the Engineers' Association. In that Association, papers were read in various towns before local branches of the organization, and then forwarded to the central society, and there discussed, and, if approved, printed and forwarded to the members of the Association generally.

The Registrar said that the suggestion made in Mr. Gregg's post card, and that made by Mr. Baker tallied very well with a letter which appeared in the CANADIAN ARCHITECT AND BUILDER a couple of months ago. The Association might encourage the delivery of papers on various subjects, which would be published in the CANADIAN ARCHITECT AND BUILDER and thus reach members who had not an opportunity of hearing them read. He noticed that all the members who did not pay their fees had something to say about hard times, and it must be borne in mind that the present was undoubtedly a time of considerable depression in business, many architects having very little work. As to advantages, it was true the resident members had the advantage of access to the library, but of that they had availed themselves to a very limited extent. As a matter of fact, the country members have been far more regular in the payment of their fees than the city members—the proportion of those who had not paid in the city being as 13 to 23, or almost one half not paid, whereas in the case of outside members the proportion was as 20 to 25, a very much better showing. Times, however seemed to be improving, and some architects who wrote to him spoke of being very full of work. Something had been said in regard to civil servants. He was not convinced that they were a class who should be conceded any special privileges. They were in receipt of a salary from the country for performing certain duties, and being in that way secured in a living, were able to make plans at a very low rate, and had in several cases come into competition with members who wished to receive adequate remuneration for their services. If any reduction was made in the fees of civil servants, some provision ought to be made to protect members from that kind of thing.

Mr. Gregg said that after what Mr. Dick had said, he would venture to ask him to second his motion, that for this year the fees of city members be reduced to $12 and those of country members to $8.

Mr. Dick regretted his inability to comply with Mr. Gregg's request; the motion did not coincide with his views at all. He did not think that anyone sitting in the present convention was sufficiently conversant with the details of the working of the Association to be able to say what the fees should be for the coming year. If a seconder could be found for the motion, he would move that the question of fees to be paid for the coming year be left to the decision of the Council with a recommendation from the Association to make them as low as possible, consistent with the proper management of the affairs of the Association.

The President expressed himself as not in favor of any temporary reduction of fees; he thought there should be a fixed and definite sum arranged which would carry along for at least some considerable time. The Association was not in a position to make any material reduction of the fees, and if it was the opinion of the Association there should be such reduction, the expenditure would have to be reduced.

Mr. Dick was unable to see the necessity of the fees being the same every year. He thought in a year when there was special legislation going on, or other action involving larger expenditures, the fees might be increased, and reduced again in years when no such need of the money was apparent. That plan was adopted in some of the friendly associations; in some instances the assessments for the coming year were based on last year's expenditures.

Mr. Kenney thought a great deal of discussion was being devoted to a matter in regard to which there was very little complaint. He thought the most expeditious way of settling the matter was to leave it in the hands of the Council.

The President said that the fact must not be lost sight of that if the amendment to the Act was secured, members coming into the Association in order to be enabled to retain the right to call themselves architects, ought to do so on a definite understanding that they would be liable for certain fees right along. He thought it would be better to maintain a definite fee. He could understand that after running for a period of five years it might be possible to make a reduction, but he thought it would be inadvisable to drop them from year to year on the experience of one year.

On motion of Mr. Gordon, the meeting then adjourned.

THE BANQUET.

On Wednesday evening about thirty members of the Association spent a thoroughly enjoyable time in the dining hall of the Queen's hotel in connection with the annual banquet. The occasion was made as informal as possible and its enjoyability seemed thereby to be enhanced.

Among the toasts, in addition to those of a patriotic character, were the following: "The Province of Quebec Association of Architects", responded to by Messrs. Gordon and Arnoldi; "The School of Practical Science," responded to by Prof. Galbraith; "The Ontario Association of Architects," responded to by Mr. Langton; and the CANADIAN ARCHITECT AND BUILDER," responded to by Mr. C. H. Mortimer. The company listened with pleasure to songs by Messrs. Webster, Gouinlock, Baker, Belcher and Commander Law, Mr. Belcher also giving in good style a recitation.

SECOND DAY.

The first article on the programme was the testing of some material in one of the testing machines of the School of Practical Science. A 6" x 6" pine post and a 3 inch wrought iron pipe were subjected to the test and broken. The members then assembled in the room of meeting to hear an interesting paper on "Iron Fireproof Construction in New York," sent by Mr. J.C.B. Horwood, a Canadian student in New York. The paper was read by Mr. Edmund Burke, who had had enlarged drawings made from Mr. Horwood's sketches, so that each point in the construction described was clearly illustrated. After the conclusion of the paper, the subject was discussed at some length by the members present, the discussion occupying the remainder of the morning. The paper and the discussion thereon will be printed in a succeeding issue.

AFTERNOON SESSION.

The President: According to this Agenda, we are now to take up new business. Any member who has any new business to bring before the Association will please mention it now. You are aware the discussion of yesterday afternoon was postponed until this afternoon, and it would be as well, perhaps, to have the whole matter gone into at the same time.

Mr. Gregg then affixed to the blackboard two maps of the Province of Ontario, and explained that he had prepared them for the purpose of illustrating a suggestion he had made to the Registrar for the division of the Province, for the purposes of the Association, into districts. He thought it would be of great advantage if the country were organized into centres. For instance, in Ottawa the Association had ten members, and in the neighbourhood there were two members. This would constitute one district. Then, in Kingston there are five members, and in that neighbourhood, in Napanee and Deseronto, two members. He would suggest that as the next division. The third would be Peterboro', in which there were only seven members. Then came Toronto, with seventy-two members, including Toronto Junction, and with Toronto he had connected Barrie and Owen Sound. Hamilton, Paris, Guelph, Galt, Welland and Thorold would form another district. The London Centre would comprise London, Stratford, St. Thomas, Petrolea, Chatham, Ridgetown, Kingsville, Windsor and Port Elgin. This was the least satisfactory division of all, because the places were so far separated, but there were not enough members to justify the formation of two Chapters. In view of the proposed legislation, he proposed the immediate taking up of this idea in connection with making a canvass in support of the proposed amendments to the Act. For instance, upon the Ottawa centre or Chapter would devolve the duty of interviewing members, not only in that county, but in Prescott, Russell, Glengarry, Stormont, Lanark and Renfrew. He thought no more efficacious plan than this could be devised for accomplishing the present object of the Association, to say nothing of what might be accomplished in other ways in the future.

Mr. Paull suggested the appointment of a committee, to see what could be accomplished along the proposed lines.

The President thought it would be better for the Convention, if the proposal was approved of, to make a recommendation to the Council for the division of the Province into these districts, and that they get the thing into working order. It would not do to have committees working who were not under the control of the Council, which was responsible to the Association. There was no doubt the Council would attend to it if such a recommendation was made. He thought if the divisions were constituted, they ought each to have an organization of their own, subject, of course, to the Association.

Mr. Gregg moved that the Council be requested to divide the country into districts and centres, in which meetings are to be held, such divisions to be called Chapters, and that the action be taken at once, with a view to such divisions being utilized in the canvass for the desired legislation.

Mr. Paull seconded the motion.

Mr. Belcher said he understood the proposal only to refer to the mode of obtaining the support of the various members of the Legislature in those districts.

Mr. Gregg replied that the formation of the Chapters was not for that express purpose; his idea was that if the country ever grew, and continued to grow, the architects, draughtsmen and young men in architects' offices in these districts might form branches of the Association in these centres, having libraries and reading rooms of their own. In the meantime, until the

legislation sought was obtained, the machinery of these Chapters might be utilized in furthering the desired cause.

Mr. Gordon considered the proposition a very radical one, and of great importance, as it would change the whole complexion of the Association, and was of opinion that it was something which ought not to be put through hurriedly. For his own part, he could perceive many points cropping up in regard to which he was not prepared to come to a decision. He questioned whether the plan would work outside of Toronto and Hamilton. While the idea was no doubt a good one for the consideration of the governing body, he thought it was something which ought not to be decided upon at the present convention, certainly not without a great deal more consideration than it had yet received. For one thing, it would necessitate further expense on the part of the members, in the way of travelling expenses going to and from the respective centres, rent of rooms, etc., and it was not well in any way to interfere with the financial position of the Association. On the whole, he thought the motion premature, and he would rather, if it were permissible, move that the whole matter be left to the consideration of the governing body, rather as a suggestion than as a resolution carrying instructions.

Mr. Burke suggested that members from the districts proposed be heard as to the practicability of the proposition.

Mr. Belcher, while regarding the plan as a good one as far as endeavoring to secure influence towards the passage of the proposed legislation was concerned, and believing that some such plan might ultimately be made to work with advantage to the Association on the lines foreshadowed by Mr. Gregg, still thought it better to wait until the affairs of the Association were in a rather more fixed condition than at present.

Mr. Power endorsed everything that had been said by Mr. Gordon. It was difficult to get members sufficiently enthused to come to the conventions, and he thought it would be uphill work to get them together in smaller numbers at local centres. The proposition might have the effect of bringing together outside members in their districts for a time, but little local troubles would crop up and put the members at loggerheads, and the thing would fail to work satisfactorily. But with a view to canvassing the country at present, he thought the proposition was a good one, although it sufficient enthusiasm existed in the districts the canvass might be carried on by individual members without the expense attendant upon any special organization.

Mr. Gouinlock seconded Mr. Gordon's motion, and expressed his entire adherence to the views of that gentleman.

Mr. Arnoldi, while approving of the idea for the purpose of interviewing and watching the members of the Legislature in connection with the effort to secure the desired change, was doubtful of the success of the other features of the proposal.

Mr. Gregg expressed his entire willingness to accept Mr. Gordon's amendment. The only objection that had been made to his proposal, however, was that the branches might be started and then die. He did not think there was any harm in starting them if they were only effective in the one thing of working for the required legislation.

Mr. Gordon described what in another organization with which he was connected are called District Conferences, in which members from the central body at stated times visit certain points in the province, and co-operate with local members in holding meetings. Perhaps some such plan might be made to work well in connection with this Association, that one or two members of the governing body should meet with local men in that way, and a deputation wait upon the members of the Legislature. He threw out this suggestion merely to show what was done in other organizations.

Mr. Wickson was of opinion that the matter might safely be left in the hands of the Council.

The President thought Mr. Gregg's idea was a good one, as was also that just suggested by Mr. Gordon. He thought the organization of the proposed chapters should be proceeded with if at all workable. If the country could be divided up as proposed, and arrangements made that some person in each district should attend to the matter of seeing the members of the Legislature, the Association could pay the actual expenses incurred in doing so. For instance, if Mr. Arnoldi, at Ottawa, could arrange to see several of the members for constituencies in that district, let his expenses in doing so be paid. The same might be done by Mr. Power in Kingston, and by others in various places. He thought, however, it would be better to leave the matter to the Council. A great many members of the Council were present, and would through the medium of the present debate be fully aware of the wishes of the Association in regard to it.

Mr. Gordon's amendment was then put to the meeting, and carried.

CHANGE OF TIME OF HOLDING CONVENTION.

Mr. Arnoldi said he experienced a great deal of inconvenience in attending the Convention at the time at which it was now held, and thought that others must be similarly inconvenienced. He, therefore, moved that the by-laws of the Association be changed, so as to admit of the Convention being held at some time in the month of December.

Mr. Townsend said he thought a notice of motion would be necessary.

Mr. Belcher seconded the motion, though personally he found no difficulty in attending in February, but he thought the general convenience might be better served by the change.

Mr. Darling thought it would be convenient to hold the Convention just before Christmas; many people during the holiday time were in the habit of visiting Toronto, and that arrangement would enable them to kill two birds with one stone.

Mr. Power preferred some time in January. Members had not always their old work finished in December, and he thought the latter part of January, before new work began coming in, was a more convenient time.

The Registrar, as a point in favor of January, said by that time the books would be closed, which would not be the case in December, unless the beginning of the financial year was changed.

Mr. Henry expressed himself in favor of the change to December, and moved that the Council be requested to consider the desirability of making the alteration.

Mr. Townsend agreed with Mr. Henry that the matter had better be left to the Council.

Mr. Darling thought the Council was being loaded up altogether too much; surely some business at least might be done in the Convention. If a change was to be made he believed in doing it now.

Mr. Burke spoke in favor of January; he thought about the middle of that month would be an opportune time. He noticed, too, that the examinations came on at a very awkward time; perhaps a change could also be made in regard to them.

The President said he thought objections to coming to the Conventions would be raised by some members, no matter at what time it was held; they were always busy when the Convention took place. As the financial year ended on the 1st of January, it would be better to have the Convention as soon after that as was reasonable and convenient. At that time members generally had their previous year's business wound up, and had not yet got into the spring work. An objection to December would be found in the fact that although at the present meeting little had been done in the way of reading papers, one of the objects of the Conventions was to secure the preparation and reading of papers of interest, and members could hardly be asked to prepare them for December. A certain amount of preparation had also to be made by the Council, which would make December inconvenient. He thought from the 7th to the 15th of January would be a convenient time.

Mr. Power moved in amendment, that the Convention be held on the third Tuesday in January, but at the suggestion of another member changed it to the second Tuesday in January.

Mr. Aylesworth seconded the motion.

After some further discussion, the President suggested the first Tuesday in January after the 10th, and Mr. Power consenting to that change in his motion, it was put to the meeting, and carried.

VOTING BY LETTER BALLOT.

Mr. Arnoldi said that even after every provision had been made for the convenience of members attending the Convention there was still a number who really were unable to come, and in order to sustain their interest in the affairs of the Association, he thought they should not be debarred from voting; he would therefore move that the by-laws of the Association be so amended as to admit of such members voting for members of the Council by letter ballot.

Mr. Edwards had great pleasure in seconding the motion, he was really very much pleased with the motion, for, as things are at present, the nomination really carried with it the election of the nominees. Somebody knew how the thing was, but the candidates themselves did not know, nor did the Association. He therefore thought that voting by letter ballot would be a step in the right direction, as it would extend the franchise to those who were unavoidably absent from the convention. He heartily endorsed the proposal.

Mr. Gouinlock differed from the mover and seconder of the motion. He regarded the opportunity of voting as an incentive to the members to attend the Convention, and, as it was difficult enough, even with the existing inducements, to get them to attend, he was opposed to doing anything like placing a premium on absence from the meeting.

Mr. Burke thought the attendance of members at the convention afforded an index as to how the Association ought to vote for members of the Council; the men who were to be found attending the meeting were those who ought to be in the Council.

Mr. Power foresaw that there would be a difficulty in connection with the letter ballot which was now experienced in reference to the nomination papers sent out; that is, there would be voting for persons who lacked the necessary qualifications, and who were ineligible. Of course such names would be struck off by the Council, but it might engender ill feeling.

The President did not think that would be found an insuperable difficulty.

Mr. Kay had no faith whatever in the letter ballot. In the Odd Fellows, to which he belonged, that method had been tried, and on two successive years had resulted in an abortive election. He saw by the newspapers, that the same trouble had been experienced by the Medical Association, and the Druggists also had the same trouble.

Mr. Belcher said that the Society of Engineers sent to each member a list, such as the members present now had, and they

just marked with a pen through each name other than those they voted for, and returned the paper to the Secretary, and on that the members of the Council were elected.

Mr. Darling enquired how many of the people to whom nomination papers had been sent had filled them up and returned them ; he thought that would be some guide.

Mr. Arnoldi did not think that would furnish any guide. He knew that in Ottawa a good deal of interest was taken in this matter of election of members to the Council, the members there consulting with each other in regard to it. As to members not showing enough interest to come to the Convention, in the case of Ottawa there were sixteen members residing there, of whom he was the only one on the committee. Now it was not that these men had no interest in the Association—they had a great interest—but, owing to the nature of their duties, they really could not get away.

The Registrar, answering Mr. Darling's q uestion, said that out of 105 nomination papers sent out, 27 had been returned.

The President said that what had just been stated by Mr. Arnoldi was in itself a possible ground of objection to the letter ballot. If the members in Ottawa united on a candidate, and determined to elect him, and there was no such combination in other places, the candidate so supported would be sure of election. Of course, if there was no such arrangement and concentration of the vote, and each member voted as the expression of his individual opinion, that trouble would not exist, but there was that possibility. Sixteen votes concentrated in that manner would have a very decisive effect on the election. Of course, what he had said regarding Ottawa might apply to Hamilton, London, or any other place, where there were a number of members.

Mr. Townsend thought the meeting together of the members in the annual convention was a matter of great importance, and the introduction of the system of letter ballot would have the effect of reducing the number of those attending the Conventions. He instanced, in support of his contention, that yesterday there were not nearly so many members in attendance as to-day, the reason being that the election brought out the members. He would regard the adoption of the letter ballot as a very great mistake.

The President said that there was no doubt a degree of hardship to the Ottawa members, in the fact that they were practically shut out from the Convention. He would now put the motion : "That the by-laws of the Association be so amended as to enable members to vote for members of the Council by letter ballot." Lost.

ELECTION OF PRESIDENT.

Mr. Darling said that if the growth of the Association continued, and it attained the position which was looked forward to, it would be an honor anyone might covet to be its President, and he felt that it would be very much better that the President should be elected by the open vote of the Association, and not merely by a vote of the Council, as was now the case. He therefore desired to offer a motion to that effect.

Mr. Edwards asked if it was the intention to have an open vote ?

Mr. Darling said that was not the intention, but that the election of the President should be decided by the vote of the Association at large, not merely by the Council.

Mr. Gordon wished to second the motion ; like Mr. Darling he thought it far better that this should be a matter in which the Association at large would take an interest, and that the man placed in the position of President should be chosen by them as the one they thought best suited to fill the office.

Mr. Darling said the proposition might necessitate some change in the constitution, because the President was the one who had to sign checks, etc., and if the President elected lived at a distance away, it would be a serious obstacle unless some alteration was made. His idea would be to elect the President more as an honorary thing and let the Vice-President do the work.

Mr. Townsend, while admitting there was a good deal to be said in favor of Mr. Darling's proposition, called attention to the fact that the Association had not the power to make such a change without first getting the Act of Incorporation changed to allow of it.

The President suggested that Mr. Darling should change his motion to a request that the Council would try to secure the change in the Act necessary to admit of voting for the President by the Association at large.

Mr. Darling thought he would make the motion as one of instruction to the Council.

Mr. Wickson questioned the wisdom of bothering the Government about any more changes to the Act. Why could not the Association suggest to the Council the name of the person they desired to see elected as President? They instructed the Council in regard to other matters, why not in regard to this ? (Laughter.)

Mr. Darling urged as his reason for bringing the matter forward, that he thought such a mode of electing the President would carry with it greater honor. He had conceived that idea and one or two other members to whom he had spoken seemed to entertain the same view. For that purpose he made it a motion that the Council take the matter up, and endeavor to secure the necessary change in the Act.

Mr. Belcher inquired if it would not be prejudicial to the object in view, of getting the word "registered" withdrawn from the Act, to make too many suggestions to the Government at the present time?

Mr. Darling said if he for one moment thought that would be the case he would not press the matter. The one essential thing at present was to get rid of that word, and if that could be secured he was willing to abandon anything else.

Mr. Belcher said it had been suggested to him by Mr. Arnoldi, who was a more wily politician than he could claim to be, that the more changes they could suggest at the one time the better, as that would have the effect of concealing what was the real point they wanted, to which there might then be less opposition. (Laughter.)

Mr. Townsend seconded Mr. Darling's motion.

Mr. Power suggested that no action be taken until the two things could be brought forward together.

Mr. Darling said no doubt if the Council found that seeking the change in regard to the mode of electing the President at all prejudiced the prospects of the other change, they would at once drop it.

Mr. Kay thought there was a great deal of sentiment about this matter. The present method of electing the President was the one pursued by all Joint Stock Associations, Agricultural Associations, and almost every other incorporated body.

Mr. Paull said that in the Old Country the Mayor of a Corporation was elected by the Councilmen in just the same manner the President of the Association was now elected.

The President said that while he personally had a good deal of sympathy with the idea, it was still the fact that if a man could be elected to the Council by the Association, he should also be capable of securing election as President of the Association. If the Association as a body was prepared to elect any member on the Council, they would likely also elect him to the Presidency as well, and the Council would certainly be in a much better position to elect a President than the members as a whole. At the same time, as far as sentiment was concerned, he favored the election of the President by the Association rather than by the Council. As a pure, downright, business question it was another matter, and he did not know but what the present method was the most straightforward arrangement. However, if the feeling of the Convention was in favor of the change, he did not anticipate any trouble on the part of the Government, who he thought were desirous of meeting the wishes of the Association. He then requested the members who were in favor of the motion, "That the Council be requested to consider this matter, with a view to having the Act changed so as to permit of the election of the President by vote of the Association," to signify their approval of it.

Mr. Townsend said he understood Mr. Darling's motion to be that the office of President should be purely honorary, and that the work should be done by a Vice-President elected by the Council ?

Mr. Darling replied in the affirmative.

The President did not think that would be right ; he thought the man who did the work should enjoy the honors ; he did not think any man would care to do the work on any other terms. Perhaps, after all, the best plan would be, after the nine members of the Council had been elected, to have a vote of the Association to elect a President from among them. He thought that would be practicable.

Mr. Henry thought it would be sufficient if the Association expressed its wishes to the Council.

Mr. Burke said that there were three members retiring from the Council each year. By the plan proposed, the Council might elect one of those men President, which would give him a fourth year, and debar another man from coming in.

The President pointed out that the Council would be elected first, and when elected would bring on a vote for the Presidency.

Mr. Burke said he was referring to Mr. Darling's motion.

The President asked Mr. Darling if it would meet his idea, to let the Association elect a President from among the nine members elected to the Council ?

Mr. Darling replied that it had occurred to him that it would be adding honor to the office of President if the election was by the Association. Of course the matter was one which would have to be put in workable shape by the Council, and he was satisfied that the Council should undertake it.

The motion as last amended was then carried.

A CIRCULATING LIBRARY.

Mr. Arnoldi said he thought it would be pleasing to the country members if the books of the Association in the library could be sent holus bolus to Peterboro', Hamilton or other places, and retained there for a stated time, say three months, to enable the local members to enjoy the advantage of using them. He tendered a motion to that effect.

The motion having been seconded by Mr. Power :

A member inquired if it was not the fact that members residing outside of Toronto could have any of these books by simply writing to the Registrar.

The President said that was the fact ; any member, no matter where he lived, by sending a card to the Registrar, could have any book in the library sent to him at once, if the book was in the library, and if not, as soon as it was returned by the member then having it out. Of books for which the demand was great, there were three or four copies in the library.

Mr. Edwards said, while the proposition seemed all right on its face, it would be necessary to send along the Librarian with the books, and to engage a room in which to keep them. The matter was now in a practicable shape, and he advised keeping it so.

Mr. Gouinlock said the proposition suggested to him the idea of a travelling dairy.

The motion was lost.

ADDITIONS TO THE LIBRARY.

Mr. Gordon brought forward a motion of instruction to the Library Committee, coupling with it a vote of thanks to that committee for the manner in which they had in the past served the interests of the Association. He thought it was highly desirable to make the library as complete as was consistent with the state of the funds of the Association, and he therefore asked that they would take into their consideration the desirability of applying a portion of the capital account to the purchase of books. (Hear, hear). It was along that line that members could be shown they were getting something for their fees. He believed that the members who had received books from the library would feel at the end of the year that they were getting a very tangible return for their money.

Mr. Paull seconded the motion.

The President stated that it was the intention of the Council that the library should be increased, but that before taking action in that direction they wished to feel that they had behind them the support of the Association in making the necessary expenditure. He quite agreed that it was better to invest some of the capital in books rather than have it lying in the bank.

Mr. Gordon said that at all events the interest on the investment in the bank, and whatever was cleared from revenue above the necessary expenses, should be applied in this way.

Mr. Burke directed attention to the fact that it would be necessary this year to draw upon capital account for legislation expenses.

The motion was carried.

REDUCTION OF FEES.

Mr. Edwards asked if anything had been done towards the reduction of fees.

The President said that matter was now before the meeting ; it was open to anyone to bring in a resolution regarding it.

Mr. Gregg moved that the fees for city members be $12 per annum, and for country members $8 per annum, and that the Council consider the advisability of making those fees permanent.

Mr. Edwards was opposed to making any distinction between city members and others.

Mr. Helliwell suggested that, instead of making any general reduction or changing the amount definitely, for the present year the Council should allow a certain discount to be fixed upon the fees.

Mr. Darling thought the idea a good one, and that the discount should only be given to those who paid their fees at the first part of the year.

Mr. Burke also thought the suggestion a very practical one.

The President thought there would be difficulty in enforcing the latter part of the proposition.

Mr. Dick asked why could not the fees for the present year be reduced as suggested in the President's address, or upon that line. Then, if any moneys were wanted for legislation, or any other special purpose, he thought members would be only too glad to respond ; he knew that as far as he was personally concerned he would be very happy to do so.

Mr. Baker thought the present fee was a very reasonable one.

The President said the suggestions he had made were based upon a fairly wide knowledge of the feelings of outside members, and he thought they were reasonable in every way. The proposed arrangement was one which would enable the Association to retain its members. He certainly thought the amount paid in fees ought to be proportionate to the benefit derived by the member. Then, at the present time men came up for the examinations, and did not enter as members, and he thought the Association ought to be in a position to force them to become members as soon as they had passed the examination. To draughtsmen who had passed the examination the payment of $5 would not be a serious thing, whereas $15 was a considerable item. He also thought that for members working for corporations, or the Government, $5 would be a very fair fee, so long as they did not practice professionally ; those who put themselves in competition with other architects ought, of course, to pay the full fee. It would not be difficult to establish whether they were doing that. He thought it would be a mistake to have the fees fluctuating from year to year, and it would also be lacking in dignity. If the fees at present were too high, he was in favor of dealing with the matter in such a way as to satisfy the members. If there was any discontent, let them state their views. As a matter of fact, he thought there was very little dissatisfaction, when it came to the point, for nearly all the members who had signed the petition had paid their fees. He knew there were some who considered their fees too high, some in the city of Ottawa, and he felt that their complaint was not without reason, because they were in the employ of the Government, and paid their fee of $10 to the Association without receiving any direct benefit in return for it.

The President then read again that portion of his address in which the fees were referred to, and continuing, said he had made the suggestions after consideration of information he had received from various sources, and he thought while the proposed reduction was a reasonable one it would not so seriously diminish the revenue of the Association as to cripple it. He thought it might at all events be made to work for four or five years, and then, if it was found desirable, the higher fee could be reverted to.

Mr. Kenny seconded Mr. Gregg's motion.

Mr. Arnoldi moved that instead of reducing the subscription, the Council be recommended to make a rebate to each of the different classes mentioned by the President, on their making application for the same.

The Registrar seconded the motion.

Mr. Arnoldi said by that method, if a man was a civil servant, and only wanted to pay the smaller fee, he could secure the rebate by asking for it.

Mr. Gouinlock was unable to see why civil servants should get any reduction.

The President said that any such reduction to members of the civil service would be on the express understanding that they were not to practice outside of their departmental work. If they were known to take even one job, they should pay the higher fee. Another point which occurred to him was, that young men starting in the city of Toronto would find an assessment of $15 would come rather heavy on them, and he thought in such cases, if they desired it, the fee should be only $10.

The President then said he would submit Mr. Gregg's motion in amendment as opposed to the other ideas, and then, if that was lost, a decision could be made between the other two.

Mr. Gregg's amendment was then submitted to a vote, and was lost.

The President then said the vote would now be between a straight fee and Mr. Arnoldi's motion.

Mr. Gordon corrected the President, and said that his resolution was, that the Council be recommended to grade the fees in general accordance with the suggestions contained in the President's address, not necessarily binding them on that line.

The Registrar suggested the amalgamation of Mr. Gordon's motion and Mr. Arnoldi's amendment.

Mr. Gordon said there was nothing in Mr. Arnoldi's motion which conflicted with his.

Mr. Burke did not think the Council should be hampered with anything of this kind. There had been a very general expression of opinion, and he thought the matter should now be simply referred to the Council to thresh out and decide what was best.

Mr. Arnoldi thought it would be well, there having been so much talk, to have a motion carried.

Mr. Burke pointed out that there would be difficulty in the grading.

The President thought these matters would straighten themselves out ; it would not do to object to a straight principle because there might be difficulty in carrying it out. He thought the best way now would be to take a vote of those generally in favor of Mr. Gordon's motion.

The vote being taken, it was shown that the meeting was generally in favor of the motion of Mr. Gordon.

Mr. Gordon brought forward a motion in favor of holding future Conventions at some place down town, which would be more convenient than the School of Practical Science.

Mr. Darling, on the score of convenience, favored the proposal to hold the convention down town, at the same time expressing his sense of the obligation the Association was under to the Government for having placed at their disposal the room in which the present meeting was held. He thought, however, if the meetings were held down town, members would be able to attend them, and at the same time give some little attention to the business of their offices.

The Registrar thought that would be a decided disadvantage, for members would then be trying to attend to things which might very well be left to another day ; he thought it was better they should prepare to devote the whole day to the business of the Convention. Further, it was not well to lose sight of the advantages accruing to the Association from being in this manner affiliated with the School of Practical Science, which was the basis of their education, and the practical advantages afforded by the use of the magic lantern, which in the able hands of Mr. Wright was of such service in illustrating papers. With it the very smallest drawing could be reproduced on a very large scale on the screen, to say nothing of the many beautiful architectural illustrations, some of which Mr. Wright had kindly exhibited during the present meeting.

Mr. Burke also deprecated the idea of removing the Convention from the School of Practical Science, on account of the intimate relations existing between it and the Association, and in view of the future objects of the Association.

No action was taken in regard to the proposal.

ELECTION OF MEMBERS OF THE COUNCIL.

The election of three members of the Council was then proceeded with. Mr. Wright, of the School of Practical Science, and Mr. Emerson, stenographer of the Convention, were requested to act as scrutineers.

Three ballots having been taken, the scrutineers declared that

Messrs. Darling, D. B. Dick and Edwards had been elected to the Council.

Mr. Symons then moved that the Council be recommended to elect Mr. D. B. Dick to the office of President.

Mr. Kay seconded the motion.

Mr. Townsend, while expressing himself fully in sympathy with the result of the balloting, and the recommendation it was desired to make, did not think in the present state of the Act it would be a proper course to adopt; he objected to the principle.

The President said if that was the case the motion would have to be dropped, as there was no power on the part of the Association to pass such a motion.

Mr. Symons being desirous, on account of the delicate health of his partner in business, to relinquish the duties of auditor, it was moved by Mr. Gordon, seconded by Mr. Burke, that Messrs. Langley and Gemmell be the auditors for the coming year. Carried.

Mr. Baker inquired if it was not in order now to nominate the committee to assist the Council in the legislation which was being sought.

Mr. Townsend asked if it had not been decided that the Council should appoint members of that committee.

The Registrar said the sense of the meeting, at the time the question was being discussed was, that the selection should be made by the Convention, but no vote was taken on the subject.

The President said it was better to have a vote on the subject, which being taken, it was found that the meeting favored leaving the appointment in the hands of the Council.

The President remarked that he felt it incumbent upon him to thank the Association for the unlimited confidence they seemed to repose in the Council.

During the progress of the balloting for members of the Council, the Registrar read a paper contributed by Mr. R. C. Windeyer, which was listened to by those present with marked interest. At its close a vote of thanks, moved by Mr. Townsend, and seconded by Mr. Belcher, was accorded to Mr. Windeyer. This paper, owing to lack of space, is held over for future publication.

On motion of Mr. Baker, seconded by Mr. Power, the thanks of the Association were tendered to Hon. G. W. Ross and the Faculty of the School of Practical Science, for the use of the building, and the courtesy extended to members by Prof. Galbraith and Mr. Wright.

On motion of the Registrar, seconded by Mr. Burke, a vote of thanks to the retiring Auditor, Mr. Symons, was carried.

On motion of Mr. Gregg, the Registrar took the chair, and a vote of thanks was then tendered to the President, amid hearty applause.

On motion of Mr. Belcher, seconded by Mr. Arnoldi, the Convention then adjourned *sine die*.

A NEW DEPARTURE.

The suggestion was made in this journal that an exhibit of materials employed in building construction would form an interesting and instructive feature in connection with the annual convention of architects.

The idea was this year taken hold of by Mr. Taylor, manager of the Toronto Radiator Manufacturing Co., who invited and received the co-operation of the following firms: The Gurney Foundry Co., James Morrison, Rice Lewis & Son, Warden King & Son, the Steel Clad Bath & Metal Co., and the Canadian General Electric Co.

The architects were given an invitation to make an inspection of the establishments of the firms mentioned on the day following the close of the convention, which invitation was largely accepted.

Entering sleighs at half-past nine in the morning, they were conveyed first to the extensive manufactory of the Gurney Foundry Co., on King street west, through which they were personally conducted by Mr. Edward Gurney and Mr. Carrick, the manager. They were shown the various styles of hot water water boilers, radiators, etc., manufactured by the company and had explained to them as far as the time at their disposal would allow the details of construction.

The next stopping point was the factory of the Toronto Radiator Mfg. Co., on Dufferin street, where with a few words of welcome they were received by Mr. Taylor, the manager, who explained that the establishment was the most extensive in America manufacturing only radiators. Beginning with the show room where finished radiators in variety of design and adapted for almost every conceivable position were exhibited, the visitors were guided through the various departments and shown the methods employed in their manufacture. In many respects these were similar to those already witnessed, but in a few important particulars, as for example the method of jointing the sections of radiators, they differed.

It was a matter of observation in both establishments that the utmost thought and attention are given to perfecting the article manufactured, while at the same time by means of labor saving machinery and devices reducing to the lowest possible point the cost of production.

At Messrs. Rice Lewis & Sons' extensive hardware establishment on King street east the company next alighted, and were shown the newest things in this important department of interior finish. Amongst these were locks of the finest quality and mechanism, door finishings of aluminum, and bronze goods with sand-blast finish and having pleasing variation in color, and which the visitors were assured would never tarnish. These goods are excellent in design and are adapted to the principal architectural styles.

Fifteen minutes after leaving this interesting establishment, the company found themselves not less interestingly employed in discussing amid artistic surroundings, the merits of one of Webb's choicest menus. The proceedings were presided over by Mr. Taylor, having on his left Mr. Gurney, and on his right Mr. Curry.

Due appreciation having been shown to "material" things, brief speeches were made by the chairman, and by Messrs. Gurney, Lee (of Rice Lewis & Son,) James Morrison, Gregg, of Warden King & Son, Booth, of the Steel Clad Bath & Metal Co., Andrews, of the General Electric Co., and Cassidey, Secretary of the Canadian Manufacturers' Association.

On behalf of the Ontario Association of Architects, Messrs. Curry and Burke expressed appreciation of the hospitality of the manufacturers and of the opportunity of acquiring information which had been afforded to the members. Mr. Curry took occasion also to thank the Manufacturers' Association for the assistance which they had given at Ottawa to the deputation of architects which some months ago waited on the Government to urge that a proper duty be imposed upon the plans of foreign architects. He hoped that in any future efforts which the architects might make in this direction they would have the support of the manufacturers.

It was pointed out by some of the manufacturers present that American and not Canadian materials had usually been employed in buildings erected in Canada by American architects, and that in consequence the manufacturers were directly interested with the architects in endeavoring to have the present condition of things remedied.

Mr. Gurney was of the opinion that the remedy would only be found in the passing of a contract law similar to the alien labor law existing in the United States. The architects were assured of the support of the manufacturers in their endeavors to secure the enforcement of a more equitable tax on foreign plans.

After a couple of hours had been pleasantly and profitably spent the round of inspection was resumed.

In the establishment of the Steel Clad Bath Co., on Queen street east, was found a young, rapidly developing and prosperous industry, vigorously managed and equipped with every facility for achieving the maximum of efficiency at the minimum of cost. The enterprise of the company extends also to the other side of the line, another factory being located in Detroit, from which the American market is supplied.

Considerable time was spent to advantage in going through the various departments of Mr. James Morrison's brass manufacturing concern, on Adelaide street west, it being one of the largest of its kind on the continent.

The show rooms of Messrs. Warden King & Son, of Montreal, manufacturers of the well known "Daisy" hot water boiler, are situated on the opposite side of the street, and here a pleasant half hour was spent. This agency is in charge of Mr. Fairbairn.

A visit was likewise made to the offices and show rooms of the General Electric Co., at 95 Front street west, where a handsome exhibit of electric fixtures was shown.

The manufacturers having engaged a section of the theatre for the benefit of the visitors, quite a number witnessed the Duff Opera Company's performance of "The Basoche."

This closed a day of unusual interest, and so agreeable and profitable did the occasion prove to all who participated, that we are assured the first attempt in this direction is likely to be repeated at regular intervals in the future.

PERSONAL.

Mr. D. B. Dick, Treasurer of the O. A. A., is at present in Europe.

Mr. J. A. Pearson, of the firm of Darling, Sproatt & Pearson, architects, Toronto, is in St. Johns, Nfld., where the firm have secured considerable work.

Messrs. Edmund Burke and W. R. Strickland have been appointed representatives of the Toronto Architectural Guild on the Toronto Technical School Board.

Robt. J. McCallum, architect, son of Robert McCallum, engineer of the Public Works Department of Ontario, died at his father's residence, Toronto, on the 12th inst.

The dead black finish which so often is used for cast iron backs and jambs for fireplaces, as well as for the ornamental iron work sold by the grate manufacturers, is not only always much admired, but it is quite durable as well. Painters are frequently asked to finish old iron work, that is to be repaired, in the same way, but they almost always look upon it as some secret process, the knowledge of which seems to be confined to the heater men. The process is really neither difficult nor secret, but is simply not a paint at all. The iron is first of all heated to redness and then plunged into a bath of linseed oil. Some of the oil appears to unite with the iron on the surface in some way, to form a chemical compound, similar in a measure to the black oxide produced by the Bower-Barff process. Another portion seems to be actually baked upon the surface of the iron, forming a sort of coating, which might perhaps be compared to the glaze which is baked upon porcelain.—*Painting and Decoration.*

CANADIAN ARCHITECT AND BUILDER.

VOL. VI.—No. III. TORONTO AND MONTREAL, CANADA, MARCH, 1893. { PRICE 20 CENTS $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),
PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.
C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
64 TEMPLE BUILDING, - - MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

THE celebration of the two-hundred and fiftieth anniversary of the founding of the city of Montreal is to take place on June 24th and four following days. The inauguration of the National Monument Building on St. Lawrence Main street will take place on that occasion.

WE hope it will not be regarded as a reflection upon the work of Hamilton plasterers that the vibration caused by the running of the trolley cars through the streets is said to have caused the plaster to fall off the walls of the buildings of that city.

MR. T. C. Keefer, the celebrated engineer, who was the Canadian Commissioner at the Paris Exposition, thinks that a very striking exhibit of Canadian Engineering as manifested in the great public works of Canada, should be shown at the Columbian Exhibition at Chicago.

IN this age of keen competition it is refreshing to come across a trade that needs not to advertise, but is advertised for. Mr. George Johnson, Dominion statistician, of Ottawa, has received a letter from Georgetown, Demerara, asking for the names of firms able to supply ready-made houses. If any of our readers are able to fill such orders, they may, by communicating with Mr. Johnson, find an opening for doing business in this line.

THE designs submitted in the final competition for the proposed Government buildings at Victoria, B. C., have been forwarded to Montreal, where they were examined by the experts, Messrs. Curry and Taylor. Mr. Curry has gone to Victoria, taking with him the drawings. After conferring with the commissioner of Lands and Works, of British Columbia, the final decision of the competition will be made. We hope to be able to publish full particulars regarding the result in our April issue.

OUR New York contemporary, *Metal*, alludes to the deceptive practice of Canadian hardware dealers in branding their goods with fictitious names of United States manufacturers. Whatever cause for complaint Americans may find in this practice, Canadian manufacturers and Canadians generally should protest against it on the ground that it implies the inferiority of Canadian manufactured goods, and perpetuates the false notion, already too prevalent, that a foreign made article is necessarily superior to a domestic one.

MUCH interest has been awakened by the publication in the ARCHITECT AND BUILDER for February of the results of the series of tests of building stones conducted at the School of Science, Toronto, under the direction of the Ontario Association of Architects. The tests included samples of both native and foreign stones. the excellent showing made by the former should be a matter of satisfaction to the quarry owners, and to architects and builders desirous of assisting to develop Canadian resources by using native material whenever its quality can be shown to be equal to that of foreign productions.

OUR esteemed Indianapolis contemporary, *Stone*, discusses in a recent issue the subject of continental union, and reaches the conclusion that such a union would mean to the United States "a distinct commercial gain unequalled in the annals of the world." Following this comes the somewhat paradoxical statement that "it would be better that formal action be taken first by Canada, the country realy most interested." In other words Canadians

are told that they should sue for the privilege of conferring upon the United States a distinct commercial gain which is declared to be unequalled in history. Canadians will appreciate our contemporary's humor.

THE architect for the new city and county buildings in Toronto, in which so much interest has centered since the disagreement with and dismissal of the contractor, has issued an advertisement inviting tenders for the completion of the contract. We are pleased to see this course taken in preference to an attempt to complete the work by day labor, for reasons previously stated, and we hope that the result will be a satisfactory arrangement under which this important undertaking may be brought with reasonable dispatch to perfect completion.

THE unsightly condition of Queen's Avenue, Toronto, has more than once been the subject of comment in these columns. It is gratifying to observe, that during the present year something is likely to be done towards its improvement. The Ontario Government propose to beautify the portion of Queen's Park in front of the new legislative buildings, which would serve to accentuate the unsightly appearance of the avenue leading thereto. The Government has been asked to join with the city in improving the avenue in a manner to harmonize with the portion of the park to which it leads. This the Government seems willing to do. We hope to see the natural beauties of the avenue supplemented to an extent which will make it a feature of pride to the citizens.

A BILL has passed the House of Representatives and the Senate of the United States, providing that in future the designing of Government buildings shall be done by private architects of recognized ability instead of under the direction of the supervising architect of the Government. The extent of this work is such that when attempted to be done in one office, it necessitates it being turned out at machine speed, and we might add, with the marks of machine manufacture upon it. Under such conditions there is no time for careful thought, with consequently the public architecture of the country, which should afford examples of the best architectural talent, is greatly inferior to the domestic work. Under the bill to which we have referred, the standard of such architecture will doubtless be greatly elevated, and with it the standard of public taste.

THE *Northwestern Architect* relates an amusing incident of an American architect who, having secured a commission from Canada, was coming into the Dominion via Suspension Bridge with the necessary plans for the carrying out of the work in his posession, when he fell into the hands of a confidence man in the form of a customs officer, who, after having extracted from him, under friendly guize, the necessary information as to the value of the drawings, etc., compelled him to pay one hundred dollars duty upon them. The architect in question was evidently what in western parlance would be termed a "tenderfoot," or in other words, one who is unfamiliar with the business of evading payment of customs duties. We would advise him to study the methods of certain architects in the eastern border cities, who, while taking out of Canada large sums in the form of commissions, have never been known to contribute a dollar in customs duties to Her Majesty's exchequer.

ADVICES from the principal cities and towns throughout Canada indicate that the volume of building operations during the season which is about to open, will probably be in excess of that of last year. In Montreal the indications point to a busy season, and in a modified sense the same can be said of Hamilton. The outlook in Toronto has considerably improved since the beginning of February, at which time it appeared exceedingly gloomy. While it is yet too early to speak with definiteness, there are prospects that a fair season's business will be forthcoming. There is great cause to hope that these prospects may be realized, as the condition of things in the city for many months past has been exceedingly trying to architects, builders and material dealers. The scarcity of work has had the effect of intensifying competition and further depressing prices which had previously reached far too low a standard.

THE interior of the Toronto public library building was recently remodelled, and is in consequence much better adapted than formerly for its purpose. In view of the expense which has been put upon the building for the purpose of increasing its attractiveness and usefulness, it is to be regretted that the means have not been discovered to prevent the public reading room from being used as a place of shelter in winter by persons of the dissipated class, whose presence in some cases is so offensive as to make the atmosphere unendurable beyond a short period. Rather than be brought in contact with persons of this class and be obliged to inhale the impure atmosphere due to their presence, the respectable reading public is forced to forego to a large extent the advantages to be derived from frequent visits to the public reading room. We can quite understand the difficulty which may be experienced in attempting to exclude the undesirable class of persons to whom we have referred, but it ought not to be an impossible task, and in the interests of the reading community it should be done.

THE importance of trifles in a contractor's business is not as fully realized as it should be, notwithstanding that if neglected they cause ruin, and if looked after will make a fortune. A brick merchant may not be particular about his bricks being one-eighth of an inch below the regular thickness, but to the builder this means he will want a considerable number more bricks to complete his job, for it will take 1125 bricks to fill the space usually occupied by 1000. Again what time can be lost by unpunctuality. A contractor employing 50 hands will lose fifteen hours per week by the loss of one minute each time of beginning work. In no trade is a good and accurate system of book-keeping so requisite as in that of building, on account of the various and multitudinous features of the business, the men and materials not unfrequently, being not under the employer's eye, and other minor matters. Whether it be a large or small business, every hour worked and all materials used should be charged to some account, and every sack, cask and package hired should be returned. The cost of every contract should be known to a fraction in order to see how the matter came out, and for guidance in future work. Attention to these matters together with great case in estimating for jobs, will prevent contractors much inconvenience and loss.

MUCH valuable information for architects and builders is contained in the paper which we publish in the present number entitled "Some Observations for Fireproof Building in New York," by Mr. J. C. B. Horwood. Canadian architects and builders have already been called upon to deal to some extent with the problems attendant upon this form of construction, and in the future may expect to be confronted with others of greater magnitude. The knowledge of this fact, is leading them to enquire extensively into the subject, and Mr. Horwood's timely contribution will be very much appreciated, more especially as it is known to be the result of the observation of one who has had exceptional opportunities for the acquirement of knowledge in this line, and who is known to be a painstaking student. In this connection it is said to be the intention of capitalists in Ottawa, Toronto and Montreal to erect iron frame structures approaching to some extent in height those in the large American cities. We regret to observe that it is declared to be the intention of the projectors of some of these buildings to employ American architects to design them and supervise their erection. Such action would be an unjust reflection upon the competency of Canadian architects, many of whom are undoubtedly as able to carry out work of this character to successful completion as any foreign architect who might be imported for the purpose.

THE recent accident at the Odd Fellows' Hall, Weston, is an instance of the foolishness of carrying out alterations to buildings without professional aid. About a year ago the members of the society decided, without the opinion of anybody who had any knowledge in such matters, to remove certain wooden posts from the room on the ground floor, which was 25×36. These posts supported two beams (10×10 each) which carried the ceiling joists, the beams being 25 feet long and resting on the posts (6×8 each) of the framed buildings by tenons only 2×8. As a substitute for the supports removed, a local blacksmith was called in to fix a 1¼ inch iron rod under each beam, joined by nuts and washers to the posts on each side of the building. These rods supported two 2½ inch iron struts about 12 inches long, set at equal distances under the beams. On the evening of the accident it appears that the people present assembled altogether in one part of the room upstairs directly over one of these beams. The iron rod beneath snapped close to one of its washers at the side of the hall, and the whole floor gave way. There was no flaw in the iron as reported, but the weight on the rod was excessive. As the upper room was not half filled at the time, the accident was plainly the result of ignorance on the part of those who carried out the alterations in the building. Fortunately the results were not so serious as they might have been. We trust the accident will serve as a lesson to those who have to do with altering existing buildings or erecting new ones.

THE Canadian Society of Civil Engineers took a very important step at its last meeting in adopting a resolution moved by Mr. Alan Macdougall, asking for a committee to consider the present status of the profession. This points to an ultimate closer bond amongst the members, and the formation of what will be practically a close profession. From the tenor of Mr. Macdougall's remarks at the meeting, the intention seems to be to have one society for the whole Dominion rather than provincial societies such as now exist in our medical, legal and land surveyors' and other corporations in the several provinces. This subject will be found to be surrounded by many obstacles which will require the most careful attention and deliberation. The interests of practitioners who are not now members of that society, although belonging to English and American, must be carefully weighed. Provision must be made to acknowledge those who are now enjoying a well earned and honorable rest; and considerations granted in view of necessity arising for the consultation of engineers on special subjects who may not be residents of the Dominion. The idea which prevails that this movement is aimed at making every engineer pass an examination, or to admit to practice only such men as now belong to the society, and as soon as they fall into arrears cut off their license, is we are confident, erroneous. We doubt not it will be to the advantage of employer and employed to have a code of professional ethics, and if the members will respond heartily to the circular which has been addressed to them, the object will likely be attained.

LEGAL DECISIONS.

It has been held in England that a barbed-wire fence next to the public way is a nuisance and the owner of same is liable for any damage happening to the public.

The master in ordinary at Toronto has given a judgment holding that where a mortgagee sells under power of sale subsequent lien holders are shut out.

An appeal has been dismissed against the judgment of Mr. Justice Rose, who held that a corporation was not liable for damages for injuries caused through a horse becoming frightened at a hammer of a pile driver used by their contractor on the highway.

It has been held in a recent lien case tried in the Toronto courts that if at the time of registration of the lien nothing is due to the contractor, there can be no lien, and that giving priority to a lien is not equivalent to enacting that the owner shall pay it whether the percentage has become payable or not.

CORRESPONDENCE.

[Letters are invited for this department on subjects relatde to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

DECORATION OF THE LEGISLATIVE CHAMBER AT TORONTO.

TORONTO, March 10, 1893.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—I have recently had an opportunity of inspecting one of the most ambitious pieces of decorative work yet attempted in Canada. I refer to the legislative chamber of the new Parliament Buildings in this city. While I cannot but admire the courage which prompted a departure from orthodox methods, it nevertheless appears to me that the idea of boldness of coloring has in this instance been carried a step too far. I would be pleased to know to what extent this opinion is shared by your readers.

STUDENT OF COLOR.

ORGANIZATION OF CANADIAN BUILDERS.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—The views expressed on the above subject by Mr. J. L. Phillips, Secretary of the Toronto Builders' Exchange, in the January number of your paper will, I think, be endorsed by all builders who have the interest and welfare of the craft at heart, the only wonder being that steps have not been taken, ere this, to bring about a closer relationship between the members of the several trades connected with, and incidental to building operations.

Canada is far behind in this matter. No doubt the unsettled state of the trade, and many of the inconveniences which builders are suffering from, would not exist if the several associations in the country relating to this line of business were brought more into touch one with the other and amalgamated under one National or Provincial Association.

Such a step would not only strengthen the trade as a body, but the experience of fellow craftsmen in all parts of the country could be obtained, which would be capable of actual individual application with good results.

The members of the building trades in Canada must be envious of their American friends meeting this month at the twelfth annual convention of the National Association of Builders, which promises so much good to all concerned. There is no doubt that such an Association in Canada, besides bringing about the improvements named by your correspondent would teach the several members of the trade the best methods of securing the establishment of equitable and profitable business conditions and would act as a strong security against unfair legislation and undesirable workmen, whether employers or employees.

It is hoped that now the subject is brought forward it will not be allowed to drop, but that the several Associations interested will come forward with their views and some steps be taken which will bring about a unity in this important department of business that will strengthen its position and place it on a more satisfactory and promising footing.

Yours truly,

AN INTERESTED BUILDER.

PUBLICATIONS.

The *Cosmopolitan* Magazine offers fifteen hundred dollars, in four prizes of one thousand dollars, three hundred dollars, two hundred dollars, and one hundred dollars, respectively, for the water colors which shall be chosen by a committee from such drawings as may be submitted by the artists of the United States or Europe on or before twelve o'clock on the first day of December, eighteen hundred and ninty-three. The subjects are to be selected from the life of Christ, taking those scenes which teach in the highest forms the lessons of love, patience, humility and forbearance, with fidelity, as far as may be, to the actual surroundings and conditions of the period. The treatment should be calculated for single page reproduction in the *Cosmopolitan*, in size five by eight inches. The subjects to be suitable, as far as possible, for use in stained glassfor church orcathedral. The originals for which prizes are awarded will become the property of The *Cosmopoliton*.

FIREPROOF PAINT.—Seventy pounds of zinc white, 39 lbs. of air slaked lime, 50 lbs. of white lead, 10 lbs of sulphate of zinc. Mix the zinc white and lime together and grind in elastic oil, then add one gallon 35° water glass, then the white lead and sulphate of zinc. Stir well. This will make white paint. If a shade is required add the necessary color.

SOME OBSERVATIONS ON FIREPROOF BUILDING IN NEW YORK.*

By John C. B. Horwood.

[The illustrations accompanying this paper may be found elsewhere in this paper upon a separate sheet.]

The law in New York city requires all buildings to be fireproof when the top of the deck roof beams (half way up the rafter for pitch roof) are over 85 ft. above the pavement.

In all iron construction, as in slow-burning mill work, I find that the most straightforward and rational method of laying out the framing scheme is the best, avoiding trimming as much as possible, and keeping heavy weights from such position as necessitates carrying them in lateral directions to find their bearing on the continuous line of supports to the foundation.

Cast iron is the principal material used here for supports, except in very lofty buildings, such as the *World*, and the 12 storey Havemeyer office building now nearing completion; though the Columbia office building on Broadway, which has some 13 floors above the basement (3 of which are in a pitch roof) has cast-iron posts. Another building now going up, adjoining the Mutual Life building on Nassau street, has about 12 stories of frame in position, the posts being cast iron.

The *Herald* newspaper building being erected in an open plot of ground at the intersection of Broadway, 6th ave. and 34th st., is but two or three stories in height (similar in idea to the Bank of Montreal in Toronto) and has all the columns wrought and riveted (fig. 1) but this is the exception in such a low building.

In a very narrow, high building there will of necessity be a certain amount of play at the bolted connections of cast iron work, which is avoided in rivetted wrought columns.

If rolled sections only are intended to be used, the spans of girders and beams must be laid out to keep within the limits of the loads to be carried, whereas the spans may be greatly increased by substituting plate girders.

Whatever scheme of construction may be used for a fireproof building, the interior framing remains practically the same; so that it becomes merely a problem of treating the external wall in its relation to the adjoining floor. There are three ways of doing this, which are optional as far as the law is concerned: 1st. By making the masonry walls and piers of sufficient strength to carry their own weight plus that of the floors, roof and contents of the building. 2nd. By making the walls and piers of only sufficient strength to carry their own weight, and framing all the floors so that their weight shall be entirely carried by iron supports or columns extending from the foundation to the roof, the columns if necessary being somewhat recessed in the walls. 3rd. By making a frame of columns and girders to completely carry the outer walls as well as the adjoining floor construction.

The first method was used in a 10 storey warehouse on Bleecker street erected about two years ago. I noticed, before it was finished, that a considerable quantity of the outer brick facing on the lower stories had been crushed by the great weight above, necessitating cutting out and replacing. The second scheme is the one most generally adopted. The last method is adopted where the utmost economy of floor space is desired; and of the three, I think it is the cheapest. A comparison of the relative cost may be easily estimated from rough sketches of each scheme, by taking (as we do) cast columns at 3½c. to 4c. per lb. and beams framed (and I presume wrought columns also) at 5c. per lb.

When the third method is adopted, the "curtain walls," if carried on girders at every story, may be 12" thick, but if on girders at every second storey, and the intermediate floor braced by metal ties, the wall must be 16" thick. The former method is the most usual—in fact, I have seen no case of the latter.

Before the building law was revised last year, the columns were allowed to project inside these walls without masonry protection (fig. 2) but now a 4" casing of brickwork is required (fig. 3).

The two following sketches (figs. 4 and 5) are copied from the Building Law, illustrating this method. Fig. 4 is the one usually adopted; I do not remember having seen No. 5 employed.

The flanges of the girders carrying the curtain walls are brought to within 2" of the outer face of the wall, the mason work being cut to fit them (fig. 6), making the masonry at the level of the girders a mere filling, resting partly upon the lower flanges of the girders, and partly upon the wall below. These girders may, of course, be of rolled sections instead of built as shown on sketch, though it is the latter that I have seen used for that purpose.

I heard the foreman of one of the largest iron firms say, that up to 20" it is just as cheap to use rolled sections—beyond that the built ones are more economical. The above sketch (fig. 6) of girders at floor level applies to all floors, as the girders over each other will be the same size unless in special cases where some extra load may necessitate greater depth and strength. The only variation is in the size of the columns at each storey, thus making the brackets and lugs larger as the sizes of the columns diminish.

The columns are usually footed as shown in fig. 7, the footing beneath being of sufficient spread to give about 4 tons weight to the superficial foot of soil. A building is being at present erected which has footings of an unusual character. The structure will evidently have an iron frame supporting the outer walls; upon the concrete bed are now being laid footings of rivetted plate girders. Immediately beneath the columns (which are of cast iron) there is a cast iron base plate the width of the column by about 4 ft. long in the direction of the girder footing. The latter is composed of two upright thicknesses of 1" metal (forming one web) about 30" deep and some 15 ft. long, with a top plate about 14" wide and a bottom one some 30" to 36" in width. These are connected to the web by angle irons and triangular-shaped stiffeners about ⅜" thick. The elevation and sections are somewhat as figs. 8 and 9. The whole of this built portion is coated with tar, and the last column, which is on the end of one of the footing plates is secured from sinking by having its footing girder rivetted to the adjoining one by means of a very thick plate about 6 ft. long on top of the upper plate (fig. 10). Method No. 2 is the most complicated one in dealing with footings, as the footings of the walls and columns usually overlap each other, making it difficult at times to get a good unified bearing beneath both—in a pier, for instance, six or eight feet long, where sometimes, of necessity the iron post is placed near one end.

With regard to interior framing, we usually make trial schemes in order to get the least amount of metal to accomplish the desired end, as this means a saving in cost as well as somewhat less weight upon the foundations. The deeper the beams and wider the span for filling gives the stiffest floor as well as the cheapest. The Pioneer Fireproof Construction Co., of Chicago, has a catalogue which gives some interesting information and experiments on this point.

The heavy printing office building which is being erected near N.Y. City Hall is calculated for 400 lbs. per sq. ft. of floor space. The beams are about 5 ft. apart and 14' 6" long, resting upon plate girders 22 ft. between the bearing. The webs of the latter are 30" deep. The former are 10" beams. The general scheme is as per fig. 11. Where a beam is connected with a circular column it is the practice to mould the latter so as to allow the beam to butt against it with a square end (fig. 13). Fig. 12 is a section through the beams looking towards girders. Fig. 13 is a section through C. C. (fig. 12) looking towards beams, and the scored section indicates the bracket to which the double girders are bolted, and which is moulded to fit the shape of the girders. Fig. 14 is a section at A. A. fig. 12 looking down, and the plates (shown square) are sometimes made circular. Fig. 15 is a section at B B, fig. 13 looking down. The above four sketches are of instances where the bottom of the beams rest upon the top of the girders. Where a heavy girder is bolted to a square column, an interior web is cast to unite the two sides, so that the pull of the top connection or the pressure of the supporting brackets will not rupture the flat sides of the columns (figs. 16 and 17). Fig. 16 is a side elevation looking towards girder, and fig. 17 a horizontal section at level of girder.

Fig. 18 shows the manner in which the brackettings on the columns of the "Columbia" building were arranged, where the columns were about 18" square at the bottom, and connected with a wide lattice girder on the inside, which carried the floor beams. As the columns diminished in size towards the top, these supporting brackets were naturally made larger to [illegible] sizes of the girders which did not alter in size, as the [illegible]y carried were the same at each floor. Fig. 18 [illegible]ion through the outer wall at level of supporting girders, and fig. 19 a horizontal section at level of lattice girder carrying floor beams.

* Paper read for the author by Mr. E. Burke at the third annual meeting of the Ontario Association of Architects.

The following extracts are from the N. Y. Building Law, and may be of interest:

"Every building used as a store, factory, warehouse, or any other manufacturing or commercial purpose, shall be of sufficient strength in all its parts to bear safely upon every superficial foot of its surface one hundred and fifty pounds in addition to the weight of the materials composing the said floor.

Good, solid, natural earth shall be deemed to safely sustain a load of 4 tons to the superficial foot, or as otherwise determined by the superintendent of buildings. The width of the footing courses shall be at least sufficient to meet this requirement.

The safe bearing load to apply to good brick work shall be taken at:—

Eight tons per superficial foot when good lime mortar is used; eleven and one-half tons per superficial foot when good lime and cement mortar mixed is used; fifteen tons per superficial foot when cement mortar is used.

All cast iron, wrought iron or rolled steel columns shall be made true and smooth at both ends, and shall rest on iron or steel bed plates, and have iron or steel cap plates, which shall also be made true. All iron or steel trimmer beams, headers and tail beams, shall be suitably framed together, and the iron girders, columns, beams, trusses, and all other iron work of all floors and roofs shall be strapped, bolted, anchored and connected together and to the walls, in a strong and substantial manner. Where beams are framed into headers, the angle irons which are bolted to the tail beams, shall have at least two bolts for all beams over 7" in depth, and three bolts for all beams 12" and over in depth, and these bolts shall not be less than ¾" in diameter. Each one of such angles or knees, when bolted to girders, shall have the same number of bolts as stated for the other leg. The angle iron in no case shall be less in thickness than the header or trimmer to which it is bolted; and the width of the angle in no case shall be less than ⅛ the depth of beam, excepting that no angle knee shall be less than 2½" wide, nor required to be more than 6" wide.

All wrought iron or rolled steel beams 8" deep and under shall have bearings equal to their depth if resting on a wall; 9" to 12" beams shall have a bearing 10", and all beams more than 12" in depth shall have bearings of not less than 12" if resting on a wall. Where beams rest on iron supports, and are properly tied to the same, no greater bearings shall be required than ⅓ the depth of the beams.

Iron or steel floor beams shall be so arranged as to spacing and length of beams that the load to be supported by them, together with the weights of the materials used in the construction of the said floor, shall not cause a deflection of the said floor beams of more than one-thirtieth of an inch per linear foot of span; and they shall be tied together at intervals of not more than 8 times the depth of the beams.

Under the end of all iron or steel beams where they rest on the walls, a stone or cast-iron template shall be built into walls. Said templates shall be 8" wide in 12" walls, and in all walls of greater thickness, said template shall be 12" wide, and such template, if of stone, shall not be in any case less than 2⅓" in thickness (the thickness of a brick—J.C.B.H.) and no template shall be less than 12" long.

All brick or stone arches placed between iron or steel floor beams shall be at least 4" thick and have a rise of at least 1¼" to each foot of span between the beams. Arches over 5 ft. span shall be properly increased in thickness as required by the Superintendent of buildings; or the space between the beams may be filled in with sectional hollow brick of hard burned clay, porous terra cotta, or some equally good fireproof material, having a depth of not less than 1¼" to each foot of span, a variable distance being allowed of not over 6" in the span between the beams. The said brick arches shall be laid to a line on centres, with close joints, and the bricks shall be wet, and the joints filled with cement mortar, in proportions of not more than two of sand to one of cement by measure. The arches shall be well grouted and pinned, or chinked with slate and keyed.

The bottom flanges of all wrought iron or rolled-steel floor beams, and all exposed portions of such beams below the abutments of the floor arches, shall be entirely encased with hard burnt clay or porous terra-cotta; or with wire or metal lath properly secured and plastered on the underside.

The exposed sides and bottom plates or flanges of wrought-iron or rolled-steel girders supporting iron steel or wooden floor beams, or supporting floor arches or floors, shall be entirely encased in the same manner."

Staircases must be of uninflammable material. They are usually made with slate or marble treads in good buildings, and cast iron in the cheaper ones. The strings are often of cast iron, and sometimes wrought iron with cast-iron brackets bolted on to make a bearing for the treads.

Shop front frames are made of cast iron, and over the breast-summer is often placed a protection of cast iron, fig. 20: attached to it by means of lugs screwed to both the covering and the girders.

Fig. 22 is a section through the first storey opening of a large building which has sills and strings of terra cotta. The soffit is formed with a wrought-iron plate bolted to the two small beams and painted. This method is quite common here, but if so desired these beams and plate may be kept up to make room for a soffit of terra cotta slabs suspended from the wrought-iron plate which supports the terra cotta architrave on the face of the walls. The frame of the opening is of cast iron, also the sash.

In referring to the new law regarding "skeleton structures," I omitted to say that no floor beams may rest upon the walls if 16" or less in thickness. The law reads thus:—"Curtain walls built of brick, built in between iron or steel columns and supported wholly or in part on iron or steel girders shall not be less than 12" thick for 50 ft. of the uppermost height thereof (fig. 21), or to the nearest tier of beams to that measurement, in every building so constructed, and every lower section of 50 ft. or to the nearest tier of beams to such vertical measurement or part thereof, shall have a thickness of 4" more than is required for the section next above it down to the tier of beams nearest to the curb level; and then downwardly the thickness of walls shall increase in the ratio prescribed for other foundation walls. When the curtain walls are *20" or more* in thickness and rest directly on the foundation walls, the ends of the floor beams may be placed directly thereon, but at or near the floor line of each storey ties of iron or steel, encased in brick work, shall rigidly connect the columns together."

Fig. 23 is a section of the terra cotta cornice of the St. Bartholomew Mission Building, 42nd street, N. Y. Few cornices are more elaborate. The I beams resting upon the wall are placed over each console. The terra-cotta facia and outer edge of moulded soffit are hung upon the flanges of the beams running parallel to the walls. The projecting beams are anchored well down the back of wall, sufficient to give at least 33% of weight of brickwork in excess of the weight of the overhanging cornice.

[Note.—It is but fair to Mr. Horwood to state that the foregoing remarks were not prepared for public reading or publication, but were sent in the shape of a letter to a friend. He kindly consented to their being read at the convention to fill a gap caused by the failure of a member to present a promised paper.—E. Burke.]

Discussion.

Mr. Paull said the Association was much indebted to Mr. Horwood for sending such a very interesting paper to be read at the Convention, and he had much pleasure in moving that a vote of thanks be accorded to that gentleman. After expressing a hope that the paper and accompanying drawings would be reproduced in the Canadian Architect and Builder, Mr. Paull pointed out as a difficulty in regard to these very high buildings, which did not seem fully explained, that, although there might be no trouble about the foundation for its support so long as you were not cramped for room, if a building 100 feet square were erected closely adjoining another property where you could not go beyond the limit of your own ground, it would not be possible to to get that proper support for the angles which could be secured when there was a large area of ground surrounding it, and the base could be extended to a considerable distance. Regarding the craze for lofty buildings which was characteristic of American cities, notably Chicago, he thought it had about reached its limit, as regulations were now being enacted to prevent the erection of structures beyond a certain height. He pointed out the danger that existed in these large and lofty buildings, even in themselves fireproof, from the burning of furniture, etc., or being surrounded by other buildings, owing to the difficulty of getting out the large number of occupants who would necessarily be within it. These, he thought, were matters worthy of consideration by architects. He then referred to the developments of recent years in the manufacture of iron for structural purposes, some illustrations of which, by the courtesy of Prof. Galbraith, they had witnessed in the experiments that had taken place this morning, by which it had been shown that inch iron was capable of sustaining a strain of 50,000 lbs.

Mr. Burke said, in regard to the supporting beam, that it was to him a surprise; it seemed to be a very weak method of carrying a column that had no support beyond it. It seemed to him that owing to the joint which was there, everything was dependent upon the plate in the top.

Mr. Belcher thought if the plates and girders were reinforced it was very much stronger than work carried through continuously, because the angle irons at the joint were double.

At the request of the President, Prof. Galbraith then explained, pointing out on the drawings some features of the construction.

Mr. Aylesworth was interested in knowing what was thought

of this combination of construction by other than American architects, as it was purely an American system. He could not but think there were weak points about it, owing to the combination of vertical iron work and masonry, of which the one would settle more or less, and the other would not. Then, in regard to the curtain walls, he noticed there was a twelve inch wall, (brick and a half) carried on a beam, about 15 feet square of masonry; he thought the support for that wall at the beam was insufficient, and did not see what was to prevent it tumbling out. It might be tied more or less, but it seemed to him a weak method of construction; either iron or masonry alone might be all right in themselves, but he did not see that they would always hold together. He had always found weakness in that kind of construction.

Mr. Paull thought the expansion and contraction of the iron under varying temperatures would affect the walls in some degree, and necessarily weaken them.

Mr. Belcher instanced the erection, with which he was connected, of a fireproof building in Liverpool some fifty years ago. It had been thought the effects of the expansion and contraction would be prejudicial, and very careful notes were made. The building had outer walls of cut stone, and brick and cement internally. The walls were supported by eight sectional cast-iron columns, and were five stories in height. The girders were cast iron, trussed with wrought iron, and brick filling springing from the flanges of the girders. The observations did not reveal the slightest appearance of crack due to contraction or expansion. Of course there were not in England the extremes of temperature to be found in this climate.

Mr. Paull said that whereas the variation in temperature in England was not more than 50 degrees, here it would be as much as 120, which must be considered in making any such comparison as Mr. Belcher had instituted.

The Registrar said that from what he had read of iron construction in the United States the objection had been found to exist there, and that iron and brick were not built together now, but the construction was a skeleton of iron entirely.

Mr. Darling said he noticed in the Canada Life building, the walls of which were quite equal to carrying the building unaided, a number of upright iron columns were built into them.

Mr. Burke said the Freehold Loan building was constructed in the same way, and also a new building at the corner of the market (Branch Bank of Commerce).

Mr. Darling questioned the utility of such a practice, and condemned it as bad construction. He thought it distinctly a loss.

Mr. Burke thought it a waste of material.

Mr. Power thought it might be as a horizontal tie.

Mr. Burke said of course that was not the difficulty in the paper under discussion, which gave the different systems. In that case there would be no contraction or expansion in the columns, the carrying power of that would be so slight as to be scarcely appreciable in the joint it would form in the brick work. In the other way, where it was carried independently altogether, then the walls were increased so that they carry their weight; practically there would be no shrinkage in that, but moving up and down inside, there might be a question about that.

Mr. Aylesworth thought the variation in a building 100 feet high would be considerable.
